Messrs. Charlesworth and Co., Haywards Heath, staged a very fine and well arranged group, containing a very large proportion of novelties. At the back were slender Oncidiums with showy Odontoglossums and brightly-coloured Odontiodas, the ends being of white Odontoglossums of the xanthotes section which orginated with the firm. The body of the group was of showy Cattleyas and Laelio-Cattleyas with heavy sprays of the large white Moth Orchid (Phalaenopsis amabilis Rimestadiana) drooping over. The group included many Miltonia crosses, and other rare hybrids specially noteworthy being Odontonia lutea (O. Magali Sander xanthotes × Odm. luteo-purpureum Vuylstekeanum) with an elegant spray of white flowers with yellow spotting; Cattleya Lord Rothschild alba with pure white flowers and purple lip; Cattleya Luegeae Triane, a grand form with very large and richly-coloured flowers; Charlesworthara Rajah (Miltonioda Ajax × Oncidium monachicum metallicum), a marvellous cross with its first flower, which is deep claret-purple with yellow base to the lip. Another grand novelty with first flower was the richly-coloured Odonto-glossum Clonius (Aquitania × The Czar).

Messrs. Stuart Low and Co. staged a very fine and varied group of good hybrids and rare species, in the centre being a very showy and interesting selection of Sophronitis crosses of various rich tints of colour. The back was of graceful Palms with slender Oncidiums, and the body of the group contained showy Cattleyas, Brasso-Cattleyas and Laelio-Cattleyas; specially handsome were Laelio-Cattleya St. Gothard var. Lord Renfrew, one of the showiest of the class, L.-C. Ortega (L.-C. labiosa × C. Dowiana) bronzy-mauve with crimped crimson lip; excellent Cattleyas of the Hardyana class, and some very large and delicately coloured Brasso-Cattleyas.

Messrs. Flory and Black, Slough, staged a group of select hybrids, Brasso-Laelio-Cattleya Rumania Majestica, with an immense delicate lavender flower; Brasso-Laelio-Cattleya Alfred Mollet var. Baron Ohara (B.-L.-C. Morna × C. Hardyana); B.-C. Viscount Sohma (C. Moira × B.-C. Ilene); and other Brasso-Cattleyas and Cattleyas were well displayed.

Messrs. Mansell and Hatcher, Rawdon, Yorkshire, had a very large, varied and excellently arranged group replete with fine Odonto-

Digitized by Google

glossums, Odontiodas, Cattleyas and Laelia hybrids. Large-flowered Miltonias and especially the white forms, were most effective and were marvels of excellent culture.

Other Exhibits.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), sent Cattleya Prince Shimadzu Rosslyn variety (Hardyana × Tityus), a grand example of one of the finest hybrid Cattleyas, of perfect form and rich colour; and Brasso-Cattleya Penelope Frenchay variety (B.-C. Madame Chas. Maron × C. Fabia), a large flower of fine shape.

A. M. Gentle, Esq., St. Albans, showed Laelio-Cattleya Edith Gentle (L.-C. Miss Louisa Fowler × C. Hardyana), a very pretty light mauve flower with white midribs to the segments and Tyrian purple lip; and a well-flowered plant of Pleione Wallechiana.

Messrs. Cowan and Co., Southgate, showed Cypripedium Bedfordiae (Actaeus revoluta × Shogun), a very handsome Cypripedium which had previously obtained an Award of Merit; and other hybrids.

Floral Committee.

Present: Messrs. H. B. May (in the chair), Wm. Morter, H. R. Darlington, John Heal, G. W. Leak, Chas. E. Pearson, G. Reuthe, G. Harrow, Hugh Dickson, J. F. McLeod, J. Jennings, W. Blakey, C. R. Fielder, D. B. Crane, Arthur Turner, J. B. Riding, W. B. Gingell, W. H. Page, M. C. Allwood, Thos. Stevenson, H. V. Warrender, Andrew Ireland, R. W. Wallace, W. B. Cranfield, H. J. Jones, Clarence Elliott, R. C. Notcutt, W. J. Bean, W. G. Baker, Sydney Morris, and Amos Perry.

Awards of Merit.

Berberis Autumn Beauty. This is a very beautiful Berberis when in fruit, as it carries an abundance of fairly large fruits, often as many as seven in a cluster, and these are pale creamy green at first, but change to brilliant coral red. The growths are very twiggy and more erect than in most Berberis. We are informed that it is a hybrid from B. rubrostilla. Raised at Wisley. Shown from the Royal Horticultural Society's Gardens, Wisley.

Ligustrum Quihoui. This elegant and free-flowering shrub attracted a good deal of attention by reason of its large Spiraea-like pyramidal panicles of tiny white flowers, produced freely towards the ends of the branches. The specimens shown were said to represent the tree form of this useful species. A very fine Privet, with narrow, shiny, deep green leaves. Shown by the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree.

Gladiolus Palestine. A very effective variety with neat spikes of pale yellow or deep cream flowers, this shade being deepest on the two smaller segments and forming a fine setting for the large rich red brown blotches. Shown by Messrs. J. Kelway and Son, Langport.

Buddleia Golden Glow.—This is one of the hybrids obtained by crossing Buddleia variabilis with the old B. globosa. The spikes bear the flowers in rounded clusters that betray the B. globosa parentage. The colour is orange and yellow, with shading and tinting of pink and mauve. Shown by W. Van de Weyer, Esq., Corfe Castle, Dorset.

Buddleia Moonlight.—Another hybrid between B. globosa and B. variabilis; the flowers are borne in similar style to those of B. Golden Glow, but they are of a light creamy shade with deep orange yellow throat. Interesting but not very attractive. Shown by W. Van de Weyer, Esq.

Aster Snowdrift.—A pure white double variety with flower heads of good size and form. As shown, it is a very free flowering variety, and because of its purity it should prove useful for the art flower trade as well as for the flower border. Shown by Mr. Ernest Ballard, Colwall.

Chrysanthemum Minstrel.—A shapely and neat Japanese variety apparently of comparatively dwarf habit. The colour is deep rosy crimson. A fine early flowering chrysanthemum. Shown by Mr. H. Woolman.

Chrysanthemum Royal Salute.—This early-flowering variety has very double flowers of rich chestnut red colouring. Shown by Mr. H. Woolman.

Chrysanthemum Doreen Woolman.—A charming single variety of capital form, and bearing large flowers of a brilliant light orange, terra-cotta shade. Shown by Mr. H. Woolman, Shirley, Birmingham.

Chrysanthemum Mrs. Jack Pearson.—This orange bronze variety is fine for garden decoration, as it flowers continuously from mid-July until severe frosts arrive. Figured and described in *Gard. Chron.* of February 3, 1923, p. 65. Shown by Mr. P. Ladds, Swanley Junction.

Carnations and Pinks.

Though somewhat smaller than at Chelsea, the groups of Carnations were of considerable size, and of distinct merit. Messrs. Allwood Bros. arranged, on staging, large vases of George Allwood, their new blush salmon, which is a good companion perpetual flowering variety to the gorgeous coloured Edward Allwood, Wivelsfield Apricot, Laddie, Maine Sunshine and Wivelsfield Claret, were also excellent. On a floor space Messrs. Allwood Bros. made an attractive turf bordered garden of their Dianthus Allwoodii, with a centre grouping of perpetual border Carnations. The former included masses of Barbara, crimson; Jeanie, pale blush; Brian, salmon pink; and Beatrice, rose-madder. This little garden was particularly happy in its conception.

Adjoining their large collection of Chrysanthemums Messrs. Keith Luxford and Co. had an exhibit of fresh and bright Carnations, which included Cheerful, rosy-crimson; Tangerine, orange; Mr. Walter Hemus, pink; and Bomb, salmon. Messrs. Stuart Low and Co. arranged a number of excellent varieties. Their Eileen Low, White Pearl, Saffron, and Red Ensign, were very prominent.

At the opposite end of the hall Mr. C. Engelmann had an imposing collection of the best varieties. This was arranged with considerable skill, and the dominant varieties were Delice, Laddie, Dora and Enchantress, of pink shades of colour, and such vivid sorts as Aviator, Belle Washburn, and Tarzan.

Chrysanthemums and Dahlias.

Messrs. Keith Luxford and Co. set up an attractive group of Chrysanthemums, both large exhibition and hardy border varieties, at the end of the hall. The former included Amy Paul Labbe, a splendid incurving Japanese bloom, with broad florets of bronzy yellow, with a golden-buff reverse, which is the dominant colouring of the fine blooms. Harry Clements is another valuable variety. It is of Lady Talbot type, made up of rather broader yellow florets. Geoffrey Henslow is a large white exhibition variety. The hardy varieties, suitable for growing out-of-doors, included Rose Chatillionaise, Verona, Harry Thorpe and Polly.

A great many hardy varieties were staged by Mr. Wm. Yandall, who had Bronze Normandy, Framfield Early White, Ernest Baltet, Shrapnel, Roi des Blancs, September Glory, Hesperis and Dolores. Chrysanthemums were associated with herbaceous flowers by Messrs. Wm. Artindale and Son, and with Michaelmas Daisies by Messrs. Dickson and Robinson.

Dahlias were extensively shown, and in spite of the fact that some districts have suffered from early frosts, the blooms were of great beauty. Messrs. Carter Page and Co. filled a large space with excellent varieties. Roy Hay, Mrs. Wurfbain, and Rev. Robinson, of the large decorative type; Signal and Masterpiece of the many Cactus varieties: Yellow Star, Nora Belle and Lady Greer are the names of only a very few of the excellent sorts they staged. At the end of the group Messrs. Carter Page and Co. arranged some very good Roses.

Collerette varieties were freely included by Messrs. Dobbie and Co. in their exhibit of Dahlias; the chief varieties were: Arran, rose with white quills; Hussar, scarlet; Glencoe, a deeper shade; with Strathmore, a rose-flushed cream of great beauty. Show and fancy varieties displayed in stands were particularly decorative, and the sorts so employed included Mrs. Langtry, Warrior and Model. Along the front of the group there were many Pompon and Cactus varieties, while at the end a small collection of well grown Sweet Peas attracted a deal of attention.

In the centre of their interesting contribution, Messrs. Jarman and Co. had a massed Rose Supreme, a lovely miniature Paeony Dahlia. Their new Joyce Goddard, a large Paeony-flowered variety of delightful orange-scarlet flushing, was also admirable. They also had a goodly number of Star, Cactus and Decorative types.

Miniature Paeony-flowered varieties of charming colours were included by Mr. J. T. West in his collection. This type included Lovely, Daydream, Conspicua, Rainbow, Neville and Dazzler.

It was several of the large Decoratives and Paeony-flowered varieties that, at first, "took the eye" amongst Mr. Chas. Turner's Dahlias. These were Toreador, Orange Bower and Phidias, and they also served to draw attention to such dainty little Pompons as San Toy, Johnnie, Mars, Censor and Ideal.

Messrs. Wm. Treseder, Ltd., had a large collection of fresh blooms of all types, Roy Hay, Mrs. Hay, President Wilson, Ebor, Anglaia and Delice of the large types. Miss Irens, a self-coloured Collarette, Mrs. Perry, a self-scarlet, and both of useful decorative size, were very charming. They also had very good boards of exhibition, Show, Fancy and Cactus varieties. Mr. John Forbes had a quantity of the dwarf single Coltness Gem, which is so valuable for bedding, with their herbaceous flower exhibit.

In a representative collection, Mr. J. B. Riding showed Mrs. C. Vaughan, Insulinde, Aquitania, Le Grand Jaune and Reve d'Armour of the large Paeonies and Decoratives, and Glut, Rhoda, Fairy, Halley and Glory of Stanhaus representing small varieties of the same type. He also had some especially good Cactus and single-flowered varieties.

Show Single Dahlias of perfect form and charming colouring were freely staged by Messrs. J. Cheal and Sons, who also specialised in their many decorative Star varieties. Amongst the larger sorts they included the Decoratives H. C. Drusselhuys and King Harold.

Stove and Greenhouse Plants.

There was no group of the ornamental stove specimens such as were important features of bygone days. In a corner Messrs. Robert Green, Ltd., had a very effective group of Palms. There were excellent specimens of Phœnix Roebelinii, P. canariensis, Cocos flexuosa, Kentia Fosteriana, and K. Belmoreana. In another corner Messrs. Green displayed well-grown specimen Bay trees.

A miscellaneous collection of greenhouse plants shown by Mr. E. H. Causer included Cyclamen persicum varieties, Bouvardias, Primula obconica, greenhouse Ferns, together with small pot plants of Veronica speciosa in variety. Trusses of Zonal Pelargoniums, both single and double flowered, were set up by Mr. R. J. Case. His principal sorts were A. J. Macself, deep purple; Golden Lion, orange scarlet; John Daniell, warm salmon pink; and Mars, crimson, of the singles; while chief among the double-flowered varieties were Baronne A. de Rothschild, semi-double Hydrangea pink; Champ de Neige, pure white; Diales, deep crimson lake; and Emperor Nicholas, white, with edging of rosy purple.

Adjoining their Carnations, Messrs. Stuart Low and Co. arranged tall plants of Acacias (Mimosas) interspersed with grand groups of Bouvardia Humboldtii and Chironia exifera. Mr. W. Bunn showed his new Cactus-flowering Geranium.

A group of glorious Begonias was exhibited by Messrs. Blackmore and Langdon, who showed grand plants and flowers of magnificent form, size, and colour, some being 8 inches

Digitized by Google

in diameter. The leading varieties were Albatross, white; Lord Lambourne, orange; Hilda Langdon, pink; Queen of the Belgians, deep pink, almost salmon pink; James Braid, crimson scarlet; and Lady Cory, a lovely salmon.

An exceedingly interesting collection of Cacti was arranged by Mr. Sidney Smith. His tall plants included varieties of Cereus, Opuntia, and Euphorbia, while the many small plants were chiefly of Mammillaria, Echinocactus, with a goodly variety of Echeverias and Sempervivums.

Trees and Shrubs.

One of the principal central spaces was well filled by Messrs. L. R. Russell, Ltd., with hardy trees and shrubs. Clematis were freely employed, and under the artificial light a group of the white-flowered Marie Boisselot was exceedingly effective. Associated with it were the varieties Princess of Wales, silvery-lilac, Lady Betty Balfour, royal purple shades, and Jackmanii rubra. Besides many of these excellent Clematis Messrs. Russell showed general shrubs, including Rhus typhina, Pittosporum, Silver Queen, and a collection of hardy Fuchsias.

Messrs. Hillier and Sons displayed a valuable group, largely of the newer Chinese Conifers, nearly all of which were represented. Their extensive Conifer collection included Pinus Armandii, P. Ayachuite, Abies religiosa, A. squamata, A. recurvata, A. Forrestii, Cupressus funebris, Torreya Myristica and Cunninghamia sinensis. Interspersed with the Conifers were several Japanese Maples, with brilliantly coloured foliage.

An effectively sober-hued group was arranged by Messrs. A. Charlton and Sons. They used Ilex crenata, Sycopsis sinensis, and the grey-green Senecio Grayi very effectively, with Eriobotrya japonica, various Cupressuses and Actinidia chinensis. The whole was attractively bordered with the variegated Veronica speciosa.

The dark green foliage of various large-leaved Rhododendrons in the group displayed by Mr. G. Reuthe well illustrated their value, even when not in flower, and in addition to their luxuriance is added the charm of the russet or white tomentum beneath. The chief of such sorts are Hodgsonii eximium maximum, and Falconeri. Enkianthus campanulatus, and Berberis Sargentiana supplied gorgeous colouring in their blood-red autumn foliage, while the clear and scarlet berries of Viburnum theiferum added to the effect. Liliums, Asters and Colchicums in great variety were also employed.

Clematis were prominent in a group arranged by Messrs. G. Jackman and Sons, whose outstanding large-flowered varieties were Betty Balfour, Marie Boisselot, Fairy Queen, Crimson King, and Jackmanii superba. They also showed several exceedingly floriferous plants of the fragrant "Maidens' Bower," Clematis flammula and C. paniculata. Many splendid blooms of Gaillardias, Sunflowers and Michaelmas Daisies were also incorporated in the collection.

Erect plants of the grey-green Cytisus proliferus made an uncommonly good effect in a flower group arranged by Messrs. Waterer, Sons and Crisp. They also had dwarf Conifers, Lilium tigrinum varieties, masses of Gladioli and Michaelmas Daisies, while, amongst the bordering of such dwarf shrubs as Erica vagans and varieties, there were many Colchicums.

In close conjunction with Mr. H. J. Jones's magnificent central group of Michaelmas Daisies Messrs. R. and G. Cuthbert had a very effective arrangement of hardy trees and shrubs. Acer Negundo variegata, dwarf Conifers, various golden and silver-leaved Hollies, Ceanothus Gloire de Plantieres and Ericas were the chief subjects.

Messrs. J. Cheal and Sons had two groups in the same sector. One contained excellent examples of topiary work, and the second was filled with general trees and shrubs. Autumn foliage of vivid colouring predominated, and the chief species were Parrotia persica, Quercus palustris, Berberis Thunbergii splendens and Euonymus alatus. Beautiful golden colour was provided by Acer japonica lacinatum and Koelreuteria paniculata.

Dwarf Conifers eminently suitable for planting in the rock garden were shown in close conjunction with alpine plants by Mr. G. G. Whitelegg and Mr. Clarence Elliott. They both had very good specimens, particularly of prostrate Junipers and the erect little glaucous upright Irish Juniper. The spreading dwarfed varieties of Picea were also shown. Mr. John Klinkert set out, near the raised bandstand, good specimens of topiary.

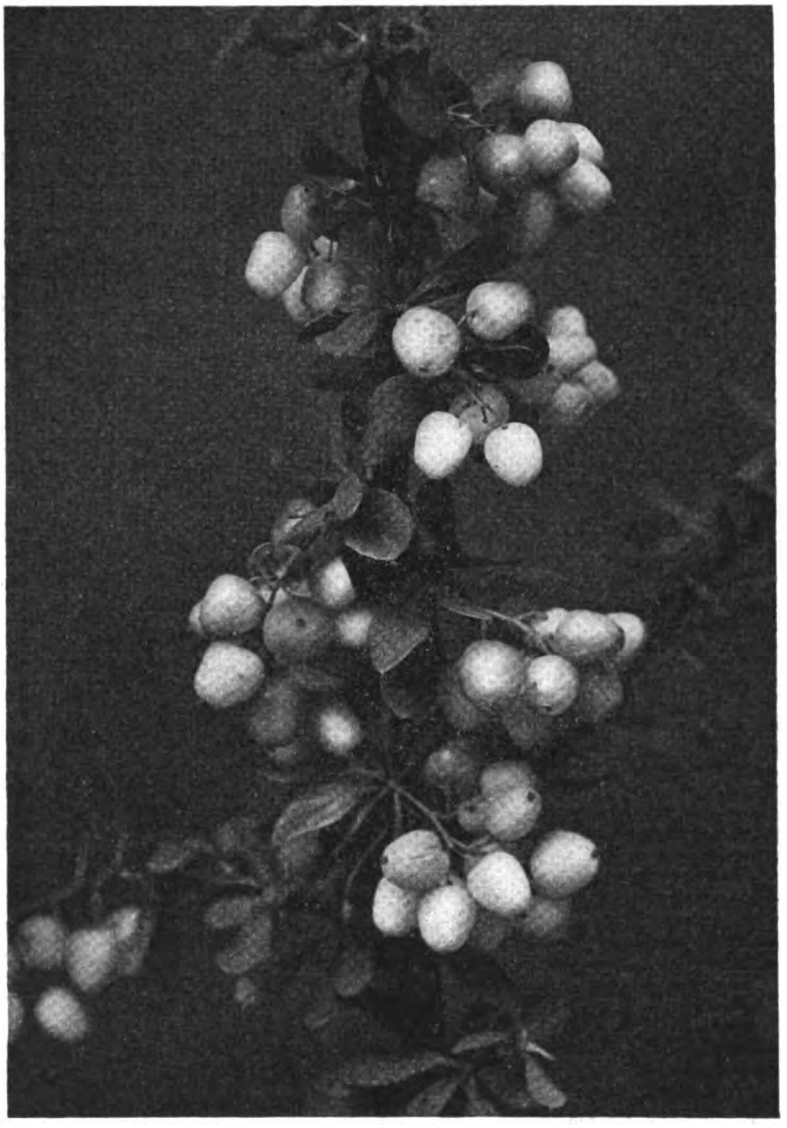

FIG. 77—BERBERIS AUTUMN BEAUTY: R.H.S. AWARD OF MERIT, OCT. 2 (SEE P. 208).

Roses.

A long stretch of tabling just inside the corridor at the main entrance was filled with beautiful Roses, and there were other groups in various parts of the hall. The arrangement by Mr. George Prince was particularly successful, and he had lovely vases of Lady Plymouth, Columbia, Golden Emblem, Etoile de Hollande, Covent Garden, and many other valuable varieties, making altogether a memorable display of first-class Roses.

A quite different style of arrangement was adopted by Mr. Elisha J. Hicks, whose chief feature was very tall columnar stands of Hugh Dickson, Golden Ophelia, Columbia and climbing Lady Hillingdon, with beautiful arches of Madame Butterfly, Ophelia and Melody. Along the front he had dwarfed masses of such sorts as Premier, W. F. Dreer and White Ophelia.

A well arranged collection was set up by Messrs. B. R. Cant and Sons, who employed masses of Emma Wright, Golden Ophelia, Mrs. E. Powell, Modesty, Hugh Dickson, George Dickson, Padre, and Mrs. Christie Miller to good effect. Such sorts as Martha Dreer, Souv. de Claudius Pernet, and Margaret Dickson Hamill were well shown by Mr. John Mattock.

Boxes of very creditable exhibition blooms were disposed along the front of their display of Roses by Messrs. S. Prior and Sons. They also staged the new dwarf Polyantha Alice Amos, single pink, with the double Alice of similar colouring. Messrs. Waterer, Sons and Crisp showed such good varieties as Los Angeles, Lady Pirrie, K. of K., Ophelia, and General McArthur.

A highly attractive group was put up by Messrs. Chaplin Bros., who used quantities of Red Letter Day, Emma Wright, Innocence, Lady Pirrie, Mrs. Henry Moore, and other desirable sorts. Varieties of his own raising were prominent in the collection of the Rev. J. H. Pemberton, with these included Nur Mahal, Mermaid, Aurora, Mary Munro and The Adjutant.

Arches of their last year's novelties, Lady Inchiquin and Betty Uprichard, were delightful in the group of Messrs. Alex. Dickson and Sons, who also displayed Lady Pirrie, Margaret Dickson Hamill, Sunstar, Betty Hulton and Shot Silk, of charming colouring.

The pink H.T., Capt. F. S. Harvey-Cant, was exhibited by Messrs. Frank Cant and Co., who also staged a good vase of the beautiful Isobel.

Roses were associated with Dahlias, Violas, and general border flowers by The Central Garden Supplies.

Adjoining their Dahlias Messrs. Dobbie and Co. staged very good vases of Sweet Peas. Considering the lateness of the season these

Digitized by Google

were very meritorious, and included such sterling sorts as Picture, Majestic Cream, Constance Hinton, Royal Purple, Royal Scot, and Hawlmark Pink. They also set up uncommonly good Zinnia blooms.

Hardy Flowers.

Herbaceous plants and flowers formed the majority of the exhibits at Holland Park Hall, and of these Asters were the predominating feature. Nevertheless there was no lack of variety in the groups which, owing to conditions favourable to second flowering, included numbers of the earlier blooming border plants.

Mr. H. J. Jones' group took the form of tall pillars of Asters, the centre one of which was crowned with a new white seedling. In addition to good examples of the Novii Belgii and Amellus groups, some fine varieties of the ericoides section were shown, one of the best of which was Florrie. Another fine exhibit of Asters was arranged by Messrs. Dickson and Robinson, whose extensive group comprised over one hundred varieties. Among others was an improved form of Lil Fardell, which was said to possess a pleasant fragrance. Some new, early-flowering, single Chrysanthemums also formed part of this fine exhibit.

Messrs. G. Jackman and Son, in addition to a good display of Clematis, among which Crimson King and Fairy Queen were conspicuous, had a representative exhibit of herbaceous plants. Bright Gaillardias, Kniphofias and Helianthus species contrasted well with the blues and lilacs of the Delphiniums and Asters, while masses of red colouring were provided by flowers of Pentstemon Southgate Gem. A large group of herbaceous plants backed by Japanese Maples was arranged by Mr. Amos Perry, in which Solidago missouriensis (given an Award of Merit on August 22, 1922, as Aster hybridus luteus—see Fig. 76), and Aster Snowdrift figured attractively.

A brilliant contrast was seen in the colours of Gentiana acaulis, and G. Farreri, together with Geum Borisi, which were seen in the group staged by Mr. W. Wells, Junr. Other interesting plants here were Eupatorium Fraseri and Trollius species. Messrs. John Waterer, Sons and Crisp showed good varieties of Asters, edged with the black-eyed Rudbeckia speciosa. The Amellus section was well represented, and included the deep blue-lilac variety Ultramarine, and a variety named Stella, which is rendered distinct by reason of its very narrow ray florets. The exhibit of Messrs. Bowell and Skarratt was by no means lacking in variety. Among other plants we noted Nymphaea albida, Clematis tangutica var. obtusiuscula, the dark blue Hyssopus aristatus, and a good form of Arabis alpina rosea.

Messrs. Gibson and Co. showed some handsome Verbascum hybrids, Pyrethrums, Gladioli, Phloxes, and some fine spikes of Lilium tigrinum magnificum. Lilies were also seen in the exhibit of Mr. Reuthe, including some examples of L. speciosum rubrum. This group was edged with species of Colchicum and enlivened by the deep red of Lobelia fulgens. Messrs. Harkness and Sons showed some good spikes of Lilium auratum and a number of Lupinus polyphyllus hybrids, the delicate shades of which were rather overpowered by the brilliant orange-scarlet and blue of other plants.

Messrs Wm. Cutbush and Son displayed Asters interspersed with baskets of Dahlias, and in the centre of their group placed a large basket of Pentstemon seedlings. The most conspicuous of the Michaelmas Daisies were the pink Ethel Ballard and the white Snowdrift. In Mr. E. Scapelhorn's group were some capital blooms of the pink Amaryllis Belladonna and of Lavatera Olbia rosea. Numbers of Gladioli were also shown. Gladioli were also exhibited by Messrs. R. H. Bath, Ltd., and attractive varieties were Yellow Hammer and Baron Joseph Hulot. Mr. H. Vigers contributed Antirrhinums, African Marigolds, and border Chrysanthemums. Some excellent Kniphofias in Messrs. Baker's exhibit included K. aloides grandiflora and K. Tuckii, which contrasted well with the violet-coloured Delphinium Mackay, with its dark stems. A bright, rose-coloured Astilbe named Granat and the white A. Beauty of Codsall, which is green in the bud state, were also attractive in Messrs. Baker's collection.

Messrs. Isaac House and Son showed a large group of their beautiful Scabious, with colours ranging from white to deep bluish lilac; while Messrs. John Forbes, Ltd., had a bright array of choice varieties of Pentstemon and Phloxes. In addition to herbaceous plants, Messrs. Maxwell and Beale staged a miniature rock garden furnished with dwarf Conifers and Ericas, the latter including E. ciliaris rotundiflora. Rock plants were also shown by Mr. Fred G. Wood and by Messrs. W. H. Rogers and Sons. In the group from the last-named firm was a spray of Skimmia oblata nana, with its scarlet fruits.

Mr. Ernest Ballard had a fine group of Asters, chiefly of his own raising, embellished with brown Bracken fronds and sprays of Golden Rod. In the centre was a big mass of the almost violet Little Boy Blue Aster. Associated with some brilliant Begonias by Messrs. Blackmore and Langdon were grand Delphiniums and other herbaceous plants. Bold groups of herbaceous plants were also exhibited by Mr. Thomas Carlile, including Hollyhocks and Phloxes; and by Messrs. Wm. Artindale and Son, who also showed a number of Gladioli. The bright group of Gladioli set up by Messrs. Lowe and Gibson was rendered very attractive by the association of sprays of autumn foliage with the spikes.

A brilliant display of hardy hybrid Lobelias made up an interesting exhibit from Messrs. B. Ladhams; the range of colour was wide and the massed effect excellent.

Messrs. James Macdonald and Sons made another of their fascinating formal gardens, solely of grasses. Amply bordered with green grass of ideal texture were beds of very highly ornamental varieties, which attracted a deal of well-deserved admiration. A little model sunken garden, with rockery, was made by Mr. Ernest Dixon.

Violets of considerable merit and in generous quantities were shown by Mr. B. Pinney and Mr. J. J. Kettle.

Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (Chairman), J. Cheal, A. H. Pearson, H. S. Rivers, W. Crump, Geo. Kelf, E. Neal, P. D. Tuckett, W. F. Giles, A. B. Dicks, G. Reynolds, F. Jordan, A. Bullock, T. Pateman, Geo. Woodward, H. Prince, N. F. Barnes, P. Veitch, J. Harrison, H. Markham, James Vert, W. Lobjoit, J. Gibson, F. Treseder, J. C. Allgrove, A. W. Metcalfe, W. Pope, E. Harriss, J. Basham, W. H. Divers, J. Wilson, Geo. F. Tinley, J. G. Weston, A. C. Smith, and A. N. Rawes.

Apple Comrade was exhibited by F. C. Stoop, Esq., West Hall, Byfleet (gr. Mr. G. Carpenter), for competition in the Bunyard Cup class, but no award was made as the Committee considered that the variety was too much like James Grieve and showed no advance.

A new variety of Grape was shown by Mrs. T. S. Hall, Crichel St. Thomas, Chard. It resembles Mrs. Pince variety and is said to be growing under trial at Wisley.

A perpetual fruiting variety of Strawberry named Boreal Giant was shown by Mr. Robert Holmes, Norwich. Flowers and ripe fruit were present on the same inflorescence which makes a big truss; the berries are round, smallish and of dark red colour. This variety is said to be on trial at Wisley.

A very promising unnamed seedling Apple sent by Mr. C. Huggins, The Chestnuts, Coldinhill, Hertfordshire, was received with favour by the Committee, who requested to see the variety again after Christmas.

Non-Competitive Exhibits.

Mr. J. C. Allgrove put up an imposing group of pot fruit trees, all cropping profusely and with samples of choice varieties of hardy fruits in baskets around the base of the exhibit. Special prominence was given to his new coloured Jefferson Plum named Allgrove's Superb, the fan-trained trees of this variety being laden with choice fruits. Exquisite little trees of Merlin Peach and others of such choice Plums as Jefferson, Coe's Golden Drop, Golden Transparent Gage, and Early Transparent Gage were all bearing choice fruits in great freedom. There were also excellent samples of such Apples as Bramley's Seedling, Newton Wonder, Lane's Prince Albert, Rev. W. Wilks and Ontario, but the most conspicuous was the rosy-scarlet cheeked S. T. Wright, a new variety sent out by Mr. Allgrove last autumn. The inclusion of Grapes, Blackberries, Rosa Moyesii, and R. Fargesii added further interest to the display.

Messrs. G. Bunyard and Co., Ltd., displayed Apples and Pears in fancy baskets of a deep mahogany colour, a tone that suggests autumn and fruit harvest time. The group was displayed for effect and the desired result was obtained, for the exhibit was one of the most notable of the many displayed in the hall. A touch of greenery with Palms and Asparagus foliage gave the necessary foil. The fruits were of first-class exhibition size, and the colour in the Apples was developed to a high degree, such sorts as Devonshire Queen, Ben's Red, Cutler Grieve, Wealthy, Red Victoria and Worcester Pearmain being coloured an intense red. The Apples embraced sixty varieties, and there were six sorts of Pears.

The Barham Nursery, Ltd., showed nearly one hundred varieties of Apples, the group having a little decoration of autumn foliage. The fruits were of fine quality generally, the more notable sorts being Cox's Orange Pippin, Bramley's Seedling, Lane's Prince Albert, Newton Wonder, King of the Pippins, Ellison's Orange, Chas. Eyre, Encore, Sir John Thornycroft, and Worcester Pearmain, the last extra fine.

Messrs. Waterer, Sons and Crisp, Ltd., exhibited pot fruit trees, the collection including a new variety of Apple, named John Waterer, a cordon tree with two fruits and another with eight fruits. The largest Apple on the former tree was estimated to weigh nearly two pounds. It was mistaken by many for Rev. Wilks' variety, the shape being like that older sort, but the colour is greeny-yellow. There were also excellent fruited trees of Ribston Pippin, Cox's Orange Pippin, Washington, Allington Pippin and Chas. Ross. The Pears included Doyenné du Comice, Conference, and Beurré Superfin, whilst a few standard trees of Brown Turkey, Negro Largo and Brunswick added variety and further interest.

The Swanley Horticultural College had a small exhibit of Apples and Pears, the fruits being remarkable for their high colouring, especially the varieties Peasgood's Nonesuch and Bismarck.

The Orpington Nurseries showed Apples and Pears in considerable variety and of fine quality. The fruits were well coloured and arranged in an attractive style. Notable dishes were Allington Pippin, Ben's Red, Peasgood's Nonesuch, Lord Derby, American Mother and Blue Pearmain.

Messrs. T. Rivers and Sons, Ltd., showed pot vines finely fruited. They were in a variety of shapes, single rods, flat-trained, and umbrella shape. The varieties were Alicante, Gros Colmar, Gros Maroc, Melton Constable, and Lady Hutt. Baskets of Apples grown under glass were displayed in conjunction with the Grapes, the fruits having that luscious, mellow appearance always associated with orchard house produce, and every fruit was a choice specimen.

Studley College showed Apples and a few Pears tastefully arranged with decorations of Rose hips, Cotoneaster frigida and Brambles. Warner's King, Peasgood's Nonesuch and King of the Pippins were outstanding dishes.

Messrs. Spooner and Sons showed some forty varieties of Apples.

The Hon. Vicary Gibbs (gr. Mr. E. Beckett) showed one of his outstanding collections of vegetables, this time the most extensive he has displayed at an exhibition. A stand similar

Digitized by Google

to the one he used at Chelsea was employed for exhibiting the various dishes, and consisted of an open trellis at the back with a floor of sea-green boards, and the back of the trellis draped with green velvet. Almost every vegetable grown in this country was shown, from Chinese Radishes to Globe Artichokes. Especially good were Leeks, Improved Lyons; Cauliflowers, Early Giant; Carrots, New Red Intermediate; Onions, Ailsa Craig; Turnip, Elstree Early; Cos Lettuce, Mammoth White; and Celeries, Aldenham White and Aldenham Pink. The group was cleverly arranged with a view to colour effect, bright tones being provided by groups of Aubergines, Tomatos, coloured Beans, golden and red kinds; Cucumbers, Chilian Beet, Sea Kale Beet, Radishes, and coloured Potatos. This fine exhibit was adjudged the best in the show and awarded the Coronation cup.

Messrs. Sutton and Sons had an exceedingly fine display of vegetables on a staging draped with black velvet. The exhibit was one of the largest in the Hall, and both in quality and style of arrangement left little to be desired. The Celeries, including Solid White, Giant White, White Gem, the earliest of all Celeries, and Sulham Prize, were marvellously good, and others that call for special notice are Student Parsnips, Sutton's Autumn Mammoth Cauliflowers, Prize Taker Leeks, Ailsa Craig Onions: Perfection, Golden Perfection and Best of All Tomatos, A.1 Kales and Gladstone Peas. Interspersed in the collection were plants of Capsicums, which gave a very decorative effect, and there were gathered fruits of Aubergines, Capsicums and Chillies, whilst in the body of the group were Cabbages, Brussels Sprouts, Lettuces, Chicory, Endive, Spinach, Cucumbers, Chinese rose-coloured Radishes and Black Spanish Radishes, and numerous other kinds. Onions were an especially strong feature in the exhibit, and embraced no fewer than thirty varieties.

Messrs. H. Chapman, Ltd., Rye, showed several new vegetables, including a yellowish Tomato with a suffusion of red, which was appropriately named Blood Orange, and Rotherside, a red variety of very even size in the truss, which bears a very large number of fruits. Orange Sunrise is another new Tomato. Rotherside Orange Marrow, which was highly commended in the trial of Marrows at Wisley this year, was also displayed, and there was a big Capsicum, Rotherside Mammoth, said to be the largest Capsicum in cultivation.

Messrs. Dobbie and Co. showed Potatos in their usual attractive style, the collection on this occasion comprising thirty baskets, each of a distinct variety. The varieties included all the standard sorts as well as novelties. As a selection we may instance Di Vernon, a new early variety, Catriona and Katie Glover, two new second early varieties; Arran Rose, a pink kidney early variety, Midlothian Early; Arran Comrade, Great Scot, and Majestic, all white kidney second early varieties; Kerr's Pink and The Bishop, two excellent late varieties.

Competitive Vegetable Classes.

The most important class in this section was that for a collection of 12 distinct kinds selected from a specified list. There were five competitors, of whom the Rev. J. Davies, Crowle Vicarage, Worcester, was easily first, with produce of remarkably fine quality and the largest size. There was not a weak dish in the exhibit. The Onions, of the Premier variety, were splendid, but some preferred the dish of Arran Comrade Potato as the best vegetable shown, and it was the finest dish of Potatos in the show. Carrots of the New Red Intermediate kind, Prize-winner Beans, Michaelmas White Broccoli, Ailsa Craig Tomatos, Selected Gladstone Peas, and Tender and True Parsnips were all of the finest exhibition quality. 2nd, Viscount Hambledon, Greenlands, Henley-on-Thames (gr. Mr. W. Turnham), whose Exhibition Brussels Sprouts, Delicacy Cucumbers, King Edward Potatos, Best of All Tomatos and Student Parsnips were of grand quality and extra large size. 3rd, E. E. Palmer, Esq., Drayton House, Basingstoke (gr. Mr. E. J. Dibben).

For a collection of nine distinct kinds, two competed, the prizes being awarded to R. Chetwynd Stapylton, Esq., Headlands, Great Berkhamsted (gr. M. W. Meager), and V. C. Vickers, Newsells Park, Royston (gr. Mr. W. Watkins), in this order. The produce in the premier collection was the smaller, and some regarded certain dishes, such as the Carrots, Onions, and Brussels Sprouts, as being much inferior to those in the 2nd prize collection, but they were in conformity with the conditions of the schedule, which stipulated "only those vegetables which are in daily use, but specially of the quality and size in which they are most acceptable and suitable for table use."

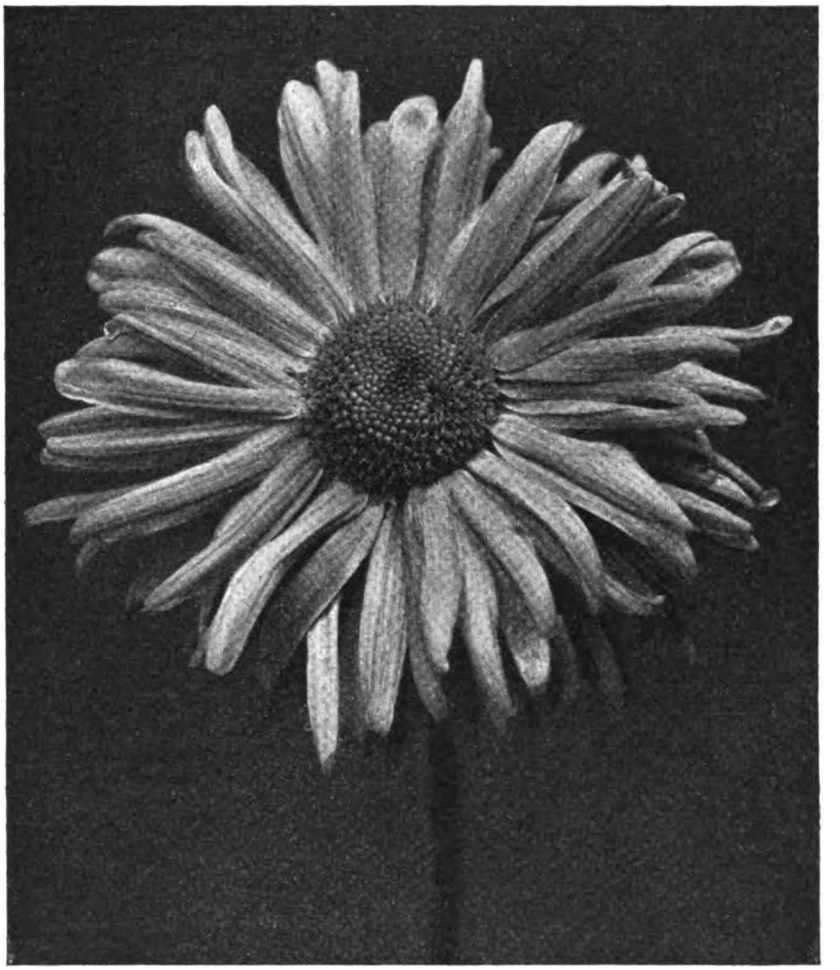

FIG. 78.—CHRYSANTHEMUM DOREEN WOOLMAN: N.C.S. FIRST CLASS CERTIFICATE, OCT. 1; R.H.S. AWARD OF MERIT, OCT. 2 (SEE P. 208).

For a collection of six distinct kinds selected from a list the 1st prize was awarded to Mr. W. Taylor, Grinshell, Shrewsbury. His Holborn Onions were extra large and of high quality, and there were fine Arran Comrade Potatos, Autumn Giant Cauliflowers, Sunrise Tomatos, Scarlet Emperor Runner Beans, and Aldenham Pink Celery. 2nd, J. Day, Esq., Berkhamsted, whose tubers of The Bishop Potato were of exceptional quality. 3rd, Mrs. Austin, Totteridge, Hertfordshire (gr. Mr. E. Longhurst).

Potatos. There were several entries in the class for a collection of 12 varieties, distinct, and the 1st prize was awarded to G. Thorn, Esq., Willesborough, Kent (gr. Mr. Hoad), for clean, shapely tubers of Renown, Arran Comrade, King Edward, Majestic, Kerr's Pink, Goldfinder, Abundance, Tinwald Perfection, and Snowball. 2nd, Sir Charles Nall-Cain, Bart. (gr. Mr. T. Pateman), with larger tubers of first-rate quality.

For a collection of six immune varieties, there were four entries, and the prizes were awarded to Mr. Head, Mr. J. Day, Berkhamsted, and Mr. R. Basil Hoare (gr., Mr. H. Penfold), in this order. Mr. Head showed Arran Comrade, Snowball, Majestic, King Albert, America and Dominion.

Onions.—The best collection of six kinds of Onions was shown by Viscount Hambledon, N. C. Vickers, Esq., Royston (gr., Mr. W. Watkins) being 2nd, and R. H. King, Esq., Berkhamsted 3rd. The largest bulbs shown by Viscount Hambledon were of Ailsa Craig variety.

The best salad vegetables, in six distinct kinds, were shown by Viscount Hambledon, who staged Cucumbers Delicacy, Blood Red Beets, Best of All Tomatos, Ideal Lettuces, Solid White Celery, and Mustard and Cress; 2nd, Mr. R. C. Stapylton.

Single Dish Classes.

The best Scarlet Runner Beans were shown by Mr. Vickers, the variety being Best of All. Mr. Palmer excelled in the class for climbing French Beans, with the variety Princess of Wales, and Mr. Palmer in that for Dwarf French Beans, with Canadian Wonder.

The finest Globe Beets were Reliance, shown by Mr. Thorn, and the best Long Beets Sutton's Black, shown by Sir Charles Nall-Cain.

Brussels Sprouts were best shown by Mr. R. H. Ling; the only exhibit of three plants of Brussels Sprouts, shown by Sir Chas. Nall-Cain, was awarded the 2nd prize.

Mr. Vickers had the best Cabbages (Savoys), Mr. Palmer the best Cauliflowers (Autumn Giant), the best Celeriac, and the best Onions. Mrs. Farnham won the first prize for Celery, with Selected Red; Mr. C. Thorn excelled in the class for Cucumbers with Everyday variety. The best Leeks were exhibited by Viscount Hambledon, with the Prizetaker variety: Marrows of the Long Green striped variety,

Digitized by Google

shown by Mr. R. H. Ling, were adjudged the best in a strong class. Tender and True Parsnips from the Rev. Davies won in the class for this vegetable, whilst for Peas Mr. R. H. Ling, with Gladstone, was placed first. Mr. Pateman showed the best white-fleshed Turnips (Snowball). Mrs. Farnham, the best red or green-topped Turnips (Manchester Market); and the Rev. Davies the best yellow-fleshed Turnips (Golden Ball). In the class for white Potatos Mr. G. Thorn scored with Majestic, and in the class for coloured Potatos Mr. Pateman excelled with King Edward variety. Mr. T. Pateman was awarded the first prize in the class for Kales. Mr. Palmer was awarded the first prize for Tomatos with Best of All variety. In the class for any other vegetable, Aubergines, shown by Mr. Vickers, and Salsafy by Mr. Palmer, were adjudged equal second, no first prize being awarded.

Competitive Fruit Classes.

There were two classes for choice collections of dessert fruits which need not be grown under glass—the one for a collection of nine dishes, the other for six dishes.

Only one exhibit was forthcoming in each class, and the first prize was awarded in each case.

The exhibitor in the larger class was Sir Charles Nall-Cain, Brocket Hall, Hatfield (gr. Mr. T. Pateman), whose fruits were of the highest merit. His Grapes were Muscat of Alexandria and Madresfield Court, shapely bunches with well finished berries. He had also Lady Palmerston and Princess of Wales Peaches, Nectarine Pineapple, Doyenné du Comice Pears, Brown Turkey Figs, Cox's Orange Pippin Apples, and a grand fruit of Hero of Lockinge Melon.

The exhibitor of the smaller collection was Viscount Hambledon, Greenlands, Henley-on-Thames (gr. Mr. W. Turnham), who showed well finished bunches of Black Hamburgh and Black Alicante Grapes; Pitmaston Duchess and William's Bon Chrêtien Pears; Apples Rival and Worcester Pearmain, and a large Melon of Queen of the West variety.

Grapes.—There were ten classes for Grapes, but no exceptional bunches were forthcoming, the quality generally being good, but not of outstanding merit. The largest class was for six distinct varieties, two bunches of each, and two sorts of white Grapes were required. It was unfortunate that one of the two exhibitors misinterpreted the reading of the schedule and staged two bunches of white Grapes instead of two distinct varieties. The first prize was awarded to W. H. Thickett, Esq., Bradley, near Grimsby (gr. Mr. J. Irving). His Muscat of Alexandria were large of bunch, but rather small of berry and greenish. Gros Colmar was extra good, and his other sorts were Mrs. Pince Alicante, Madresfield Court and Cannon Hall.

G. Mayer, Esq., Wistlers Wood, Woldingham (gr. Mr. W. Sayer), who was disqualified, had finer Muscats and excellent bunches of Mrs. Pince and Prince of 'Wales.

No entry was forthcoming in the class for three varieties if Grapes.

In the class for Black Hamburgh, the only exhibitor, E. Mayer, Esq., was awarded the 2nd prize, and this exhibitor was first in the class for Mrs. Pince and Prince of Wales.

Viscount Hambledon excelled in the class for Muscat of Alexandria, in which there were five competitors, Mr. Mayer being second.

No entry was forthcoming in the class for any other black Grape, but for any other white Grape Mr. Thickett was awarded the 1st prize for Cannon Hall and Sir Chas. Nall-Cain the 2nd prize for Lady Hutt.

Fruits Grown Entirely in the Open.

There were four classes for Apples, but competition was not so good as usual, and in the one for twelve dishes, distinct, eight culinary and four dessert sorts, there was no entry. There were two good collections in the class for twenty-four varieties, sixteen cooking and eight dessert, and Sir Charles Nall-Cain won the first prize with splendid fruits of such sorts as Wealthy, Rival, Lord Derby, Peasgood's Nonesuch, and Ellison's Orange. This exhibitor also excelled in the class for six distinct varieties of culinary Apples in competition with three other growers. The Earl of Bessborough showed best in the class for six varieties of dessert Apples, the number of entries totalling five. It is a matter for regret that no entry was forthcoming in either of the classes for eighteen dishes of dessert Pears; nine dishes of dessert Pears; three dishes of Plums; three dishes of Damsons or Bullaces; or Morello Cherries. The shortage of Pears and Plums is probably partly accountable, but the small value of the prizes may also have had some effect. The only exhibit of autumn Raspberries was from Capt. Drummond, who was awarded the first prize, and this exhibitor was successful in the class for Figs with good specimens of the Brown Turkey variety.

District County Classes.

It is to be regretted that interest in these special county classes has fallen greatly, and on the present occasion there were only eight entries from the whole of the English, Scottish and Irish counties as well as the Isle of Man and Channel Islands.

Such an important fruit-growing county as Kent did not supply a single entry, and there was only one from Surrey, Sussex and Hampshire. Capt. Drummond, Cadland Park, Southampton (gr. Mr. E. Smith) was the exhibitor and he won the first prize for both Apples and Pears. In the Wilts, Dorset, Somerset, Devon and Cornwall section there was again only one entry, and this for Apples only, the exhibitor being J. A. Stidson, Esq., who was awarded the first prize. In the class open to growers in Gloucester, Oxford, Bucks, Berks, Beds, Herts and Middlesex, the first prize went to Mrs. Austin, Totteridge (gr. Mr. E. G. Longhurst), while in the class open to growers in Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffs, Shropshire and Cheshire, the sole entry was from Mr. W. Taylor, who gained the first prize. In the class open to growers in Worcester, Hereford and Monmouth, E. Evans, Esq., was successful with Apples and Mr. T. Jones with Pears. The Earl of Bessborough, the only exhibitor from Ireland, won first prize in the class for Apples.

Two special classes were provided for amateurs possessing a total of not more than twenty-five Apple trees. In the class for six fruits of one dessert variety Mr. W. West was placed first of three competitors, with good fruits of Cox's Orange Pippin. In the class for one cooking variety E. A. Watts, Esq., won the first prize with The Queen variety.

*** *A report of the single dish classes for fruits will be given in the next issue. The awards made by the Council are given on p.* ix.

Obituary.

William Coomber.—After a few days' illness, Mr. W. Coomber peacefully passed away at Teddington, Middlesex, on September 21. He was in his eighty-fourth year. He survived his wife only three weeks, and his loss, together with the anxiety experienced during her painful illness, evidently hastened the end. The funeral took place at Ticehurst, on September 26. Mr. Coomber leaves a son, and two daughters to mourn his loss. He was the only brother of Mr. Thos. Coomber, V.M.H., who recently retired from the charge of The Hendre Gardens, Monmouth, and who received valuable assistance from him in the early days of his horticultural career. Mr. William Coomber was a native of Kent, having been born near Tonbridge. He commenced his career as a school teacher, but owing to the unsatisfactory state of his health at that time, he was advised to take up an outdoor vocation. As a beginning he entered the nursery of Messrs. W. Wood and Son, of Maresfield, where he remained some few years, and after leaving there spent some time as journeyman and foreman, in private gardens. He was in the Royal Gardens, Kew, for two years, while Mr. Smith was curator, and also served in Messrs. Henderson and Son's St. John's Wood Nursery. His first position as head gardener was at Encombe, Sandgate, but holding this for less than two years he was offered the charge of Knole Gardens, Sevenoaks, by the Countess De la Warr, who remembered him as a schoolboy, and also as leader of the choir of St. Michaels Church, Withyham, Sussex. He stayed at Knole ten years, when he was appointed superintendent of the Royal Botanic Gardens, Regents Park, an appointment he held twenty years, leaving in 1896. Here, as at Knole, his unassuming disposition and general kindliness won him many friends. Subsequently, for nine years, he managed the Pashley (Ticehurst) estate for Miss Wetherell and Mrs. Darby, and left there only when the estate was sold, since which time he has lived in retirement.

ANSWERS TO CORRESPONDENTS.

Agricultural and Horticultural Instruction: *W. W.* Write to the Ministry of Agriculture, 10, Whitehall Place, S.W., for particulars of the scholarship schemes in agriculture and horticulture.

Carnation Plants Diseased: *W. S.* The specimens were dried up and withered when they reached us. They did not, however, have the appearance of being attacked by a fungous disease. We certainly advise you to raise new plants from a clean stock, as suggested, and burn all the old plants.

Clematis Diseased: *T. J. F.* The specimen you sent was dried when it reached us, but an examination showed that the mycelium of some fungus was present, although which it was not possible to determine. Clematis are very subject to basal stem rot, and it is always a good plan to plant them in a position where the base of the stem and roots are shaded from bright sunshine.

Evergreen Hedge for a Smoky District: *G. H. H. W.* Thuja Lobbii (syn. gigantea) is to be recommended for forming an evergreen screen or hedge for planting in smoky localities in the Midlands. T. orientalis succeeds better in the London area, but the flame-shaped growths render it unsuitable for hedge purposes. If not too smoke-infested, the Evergreen Oak makes a good screen tree, but is rather slow of growth for the first ten years. Both Phillyrea and Osmanthus are valuable evergreen shrubs for town planting.

Exhibition Schedule: *B. E. H.* We have no knowledge of the show to which you refer, but you would doubtless be able to obtain information on application to the Secretary, Crystal Palace, Sydenham.

Melon Diseased: *W. F.* The fruits having cracked, bacteria and the mycelium of some fungus have affected the flesh. These, however, are probably only secondary agents in producing the disease. The splitting of the fruit is due to some wrong cultural treatment, such as an excess of moisture following drought.

Names of Plants: *L. G. D.* 1, Colutea arborescens; 2, too withered to identify; 3, Teucrium fruticans; 4, Saponaria officinalis; 5, Senecio Gravii; 6, missing; 7, Nandina domestica; 8, Cydonia japonica; 9, Euonymus japonicus var. albo variegatus; 10, Spiraea chamaedrifolia; 11, Olearia stellulata; 12, Spiraea Thunbergii.—*A. N.* 1, Rubus xanthocarpus; 2, Tilia platyphyllos var. asplenifolia; 3, Clematis heracleaefolia; 4, Fagus sylvatica car. heterophylla; 5, Acer creticum; 6, Catalpa bignonioides; 7, Rhamnus alnifolius; 8, Acanthopanax ricinifolium.

The Holland Park Hall Exhibition.

Judged by the results as a whole, the Fellows of the Royal Horticultural Society will be satisfied with the "great autumn meeting" held in the large hall at Holland Park on October 2nd, 3rd and 4th. The attendance was satisfactory, even on the second day, when rain fell almost continuously, but the number of visitors was nothing like so large as at the spring shows or, indeed, at some of the Holland House exhibitions of past years. This autumn show is regarded as a combination of the old Holland House and the Fruit and Vegetable Shows, but many will be disposed to consider it merely a glorified fortnightly meeting, lacking, in a large measure, the special features which the Holland House and the Fruit and Vegetable Shows supplied. No criticism can be levelled at the Council on account of the unsuitable character of the building, as it is probably the best that can be obtained of a size sufficient to accommodate such an extensive show, but the lighting is very poor and inadequate to show off the colours of the flowers that were on view. Whilst generous masses of border flowers, such as Michaelmas Daisies, Chrysanthemums and Dahlias are always attractive, we think the first-named were too numerous at Holland Hall and pushed into the background some of the more interesting but less obtrusive exhibits, such as the collections of Begonias, stove and greenhouse plants and Carnations. Fortunately the season has suited the late blooming of Roses and we never remember having seen finer Roses exhibited in autumn than at Holland Park Hall, but these again were not given the prominence afforded the hardy flowers, being relegated to the sides where the light was even poorer than in the centre of the building. Such special shows as these have always in the past attracted fine groups of various subjects from amateur growers, but on this occasion the amateur element was sadly lacking; indeed, the show was almost wholly composed of traders' exhibits. We are glad in this connection to note that an amateur, the Hon. Vicary Gibbs, was adjudged to have the best exhibit in the show in his marvellous collection of vegetables of almost faultless quality, and both Mr. Gibbs and his capable gardener, Mr. E. Beckett, are to be congratulated on their well-deserved success. But we missed the fine collections of pot fruit trees and indoor fruits which amateurs were wont to stage, and the numerous interesting exhibits of flowers which keen amateur gardeners used formerly to display whenever the R.H.S. held a big event of this character. Of fruit exhibits from nurserymen there were several, and most of them deserving of the highest encomiums, whilst the splendid exhibit of vegetables by Messrs. Sutton and Sons was worthy of high praise, but evidence of a special fruit and vegetable exhibition was lacking in the main body of the hall, for the competitive classes for both these subjects were all relegated to the gallery and a large proportion of the visitors never suspected their presence. This seems to us a pity, for one of the great objects of a flower show is ocular demonstration of the quality which may be obtained by high cultivation, first-class exhibits setting a high standard for those who come merely to inspect. It is, moreover, always noticeable how at flower shows professional gardeners exhibit the keenest interest in high cultivation and in many respects the special Fruit and Vegetable Exhibitions of the R.H.S. were "gardeners' shows," being held at a time when London is practically empty and those who patronise the Chelsea show largely on holiday in Scotland and elsewhere. Whether the secondary place afforded both the fruit and vegetable exhibits, or whether the meagre prizes are responsible for the great falling off in the competitions is a matter for conjecture, but we think that both have a bearing and that it would be wise to bring at least some of the more important of the fruit and vegetable exhibits into the body of the Hall another year, and to revise the lists of cash prizes in accordance with the times, for in some cases the prizes offered were not equal to the expense of bringing the exhibits to London and staging them. It seems a great pity that such a prominent horticultural society as the R.H.S. should not be able to attract better exhibits of Grapes than were seen at the recent show; indeed, we have no hesitation in saying that the quality of the Grapes was scarcely equal to that seen at a moderate provincial exhibition and certainly in no way approaching the quality found at Shrewsbury at an earlier date. Then again, collections of choice indoor fruits, for which two classes were provided, were represented by only one exhibit in each case. The keen competition that resulted at one time in the County Classes seems to have gone entirely and one wonders why such an important fruit-growing county as Kent did not send a single exhibit of either Apples or Pears in the County Classes! Even in the single dish classes the falling off in the number of entries was most noticeable, and the same was true in the vegetable section. It will be a thousand pities if the Royal Horticultural Society allows the interest in the special Fruit and Vegetable Exhibitions to lapse and we urge the Council to give the matter its serious consideration and to see how interest in them may be revived—always assuming the Council desires such a revival.

The Dahlia in Holland.

During our recent visit to Holland the outstanding floral feature which presented itself was the wonderful way in which the Dahlia has captured the Dutch people. As a flower for garden decoration the Dahlia is steadily increasing in popularity in our own country, and it will become more and more popular as raisers devote greater attention to the production of varieties which commence to flower early, produce an abundance of flowers on long stems carried well above ample leafage, and continue to bloom satisfactorily until frost comes. The number of varieties grown in Holland appears to be somewhat limited, but, doubtless, more varieties are cultivated in private gardens than are to be seen on the markets and in public parks. It appeared as though the Dutch raisers had almost given up the large and somewhat floppy Paeony-flowered varieties which they boomed a few years ago, and that they have practically dropped the cultivation of Cactus varieties. So far as we were able to judge the Decorative and the larger-flowered Pompon varieties are those which have captured the popular fancy and have, indeed, become the fashion as September flowers in Holland. On a September morning not less than eighty per cent. of the flowers submitted for Dutch auction at one of the flower markets at Aalsmeer were Dahlias, and these were presented in a remarkably fresh condition. At Aalsmeer most of the flowers are brought to the markets from a comparatively short distance, but after their sale they are despatched to the principal towns and cities of Holland, where, judging from the examples we saw in hotels and restaurants, they arrive in a fresh condition. White, yellow, mauve, pink, orange and scarlet varieties appear to be those most in favour, and in every case the blooms are compact, hence one of the reasons why they travel so well. In the open street markets at Amsterdam and The Hague, Dahlias were equally as prominent as in the cut-flower markets at Aalsmeer, while in the public parks and open spaces at Amsterdam, The Hague, Rotterdam, and Haarlem, Dahlias were to be seen everywhere. It was also interesting to observe that the shopkeepers in the principal cities and towns used Dahlias freely in their shop windows to enhance the display of goods they offered for sale, and this utilisation of natural flowers for such purposes is a point to be commended to British traders who, unfortunately, are inclined to use artificial flowers for this purpose. In private gardens, also, the Dahlia is grown quite freely in Holland, and in private houses the flowers are used for decoration as freely as we use, say, Roses, Gladioli and summer-flowering Chrysanthemums. In the display of Dahlias at exhibitions it is probable that we have not much to learn from Holland, as boards are fast giving place to vases as receptacles for the display of the blooms. In Holland, however, very large vases and large baskets are mostly used for the exhibition of Dahlias, and very rarely is more than one variety used in a receptacle. The Dutch raisers and growers have advertised Dahlias freely in Holland as elsewhere, and they appear to be reaping the reward which follows wide publicity.

Presentation to M. Viger.—Our readers who know something of French horticulture will not need to be reminded of the high position occupied by M. Viger, formerly Minister of Agriculture, and who, for nearly a generation, has occupied the post of president of the National Horticultural Society of France. M. Viger has long been recognised as the doyen of French horticulturists, and in that capacity he has visited and taken a most prominent part wherever French horticulture has been represented at home and abroad. He has now reached his 80th year, and his colleagues, to mark the high sense of their appreciation of his services to the society in particular and to French horticulture in general, organised some few months ago an influential committee for the purpose of raising the necessary funds to commemorate, by a lasting memorial, their high appreciation of M. Viger's many services. The subscription list, which has met with a very generous reception, has now been closed, and it is proposed with the proceeds to erect in one of the halls of the society a bronze bust of their eminent and highly-respected president. In the meantime, the French Government, in recognition of M. Viger's important services to horticulture in France, has promoted him to the rank of Commander of the Legion of Honour. There is thus a double reason for his numerous friends to rejoice, and it is proposed to hold a special gathering of all persons interested in the event, in the large hall of the National Horticultural Society of France, 84, Rue de Grenelle, Paris, on Thursday, the 18th inst., at 3 p.m. M. Chéron, the Minister of Agriculture, will preside, and we have no doubt that the function will be, as it deserves to be, a most brilliant success.

Orchid Shows.—At the meeting of the Orchid Committee on September 18 the Chairman, Sir Jeremiah Colman, Bt., read a communication from the Hon. H. D. McLaren advising that the Committee should consider the question of asking the Council of the Royal Horticultural Society to set aside certain dates of the year on which one or other of the larger genera of Orchids should form the special feature. The suggestion was well supported by the Committee and the Chairman discussed the matter with the Council. At the meeting on October 2 Sir Jeremiah Colman reported that the Council had agreed to offer facilities for the showing of special genera in rotation, beginning with Cypripedium, Cymbidium, Odontoglossum and Cattleyas in 1924, the Cattleyas to be the special feature of the Orchid show at the end of October, which is now an annual event. Details will be worked out and the result published in the *Arrangements of the Royal Horticultural Society* for 1924.

Lake in St. James' Park.—It is unfortunate that, after spending £31,700 on concreting the bed of the lake in St. James' Park, London, the water will not remain at its proper level, there being a loss of some three inches of water each day. It was hoped that the original concrete bed would prove sound, as from appearances it seemed unaffected by the purposes to which the bed was put during the war, and the lake was filled with water in such hope, but the water, some millions of gallons, trickled away, proving that the concrete had perished. The cause of the trouble has now been ascertained, and the Office of Works states that the source of the loss of water is found to be limited to approximately two square inches of the area of over ten acres. The leakage was discovered by isolating sections of the lake by means of submerged barriers after the water had been lowered about seventeen inches for the purpose of investigation.

A Potato Champion.—Mr. Jasper Davis, of Bromham, Wiltshire, is well known in the West of England as a highly successful small-holder and Potato grower. He has exhibited collections of Potatos for over ten years and has never been beaten, though in classes for one variety only his exhibits have occasionally been surpassed. He was awarded two first and one special prize for hundredweights of Potatos at the Crystal Palace last year, and has received many prizes for the best acre of Potatos. For five years in succession he won the two first prizes in open competition at Chippenham, and he has won seven first prizes for Potatos this year. He has a large collection of cups, shields and medals won by him outright in competitions extending over three years.

Jonkheer G. F. van Tets.—There was no more outstanding personality than that of Jonkheer G. F. van Tets at the recent International Horticultural Congress held at Amsterdam, and it is not too much to state that most of the extraordinary success of the gathering was due to him and to the able Congress Secretary, Dr. M. J. Sirks. Jonkheer van Tets is the President of the Royal Netherlands Horticultural and Botanic Society, which is under the high patronage of Their Majesties Queen Wilhelmina and the Queen Mother of the Netherlands, and has its headquarters at Amsterdam. For ease of working and to secure a thorough representation of every branch of horticulture, which finds a prominent place in Holland, the Society is divided into sections; thus, there is the Aalsmeer section, which con-

JONKHEER G. F. VAN TETS.

cerns itself principally with the cultivation of cut flowers for market; the Haarlem section, which deals principally with bulbous plants; the Amsterdam section, which takes a special interest in florists' flowers; the Westland section, which devotes attention to fruits; and the Boskoop section, which is concerned with the production of trees and shrubs for export. It will be seen, therefore, that the President of such an organisation has no light task, but the high esteem in which he is held and the great regard all members have for him show how admirably he carries out his duties. Jonkheer van Tets has a delightful garden at his home at Zeist, to which he invited the members of the Congress on September 23. The British members of the Congress, most of whom had met Jonkheer van Tets at The Hague Conference of 1922, were so charmed with his business ability and his kindliness that they have taken advantage of the opportunity afforded by his marriage to present him with a handsome silver Rose bowl as a token of their appreciation and to commemorate at once his wedding and the jubilee of the Society over which he presides.

Welsh Red Clover.—Experiments carried out at the Welsh Plant Breeding Station, Aberystwyth,* during the past four years, demonstrate in striking manner that the strain of Red Clover known as Montgomeryshire Red, and grown around Welshpool and over into Shropshire, near Chirberry, is superior in its persistence to all foreign Red Clover, and only equalled by the similar strain grown in Cornwall, and known as Cornish Marl Red. Thus, whereas both these strains give full yields in the second harvest year, other strains of foreign origin tested beside them gave only 46, 24 or 0 per cent. Another Welsh Red Clover which has proved its value is the Vale of Clwyd Late Flowering Clover. Those who require seed mixtures for pastures which are to be down for three or more years should study the article and include one or both of these strains in their mixtures.

* See *Journal* of the Ministry of Agriculture, XXX., No. 6, Sept., 1923.

Distribution of Surplus Bedding Plants in the London Parks.—The surplus bedding plants at the London County Council parks will be distributed to the public between the hours of 9 a.m. and 11 a.m. on Saturday, October 20, 1923. Those desiring to participate in the distribution should make personal application to the officer in charge at the various parks. Plants will not be handed to children under the age of fourteen years unless they present a note from their parents or teachers.

Prince Shimadzu.—After the great earthquake in Japan it was reported that Prince Shimadzu was amongst those killed. His many friends in England will be glad to know that it is now officially stated that he is alive and in good health. Prince Shimadzu is a great lover of Orchids and was for a year or more before his return to Japan an honorary member of the Orchid Committee of the Royal Horticultural Society and regularly took his place at the meetings. He is well known to orchidists generally, having visited most of the chief collections in this country.

Appointments for the Ensuing Week.—Monday, October 15: National Chrysanthemum Society's Floral and Executive Committees meet. Tuesday, October 16: Royal Horticultural Society's Committees meet; Sevenoaks Gardeners' Chrysanthemum Society's meeting; Winchester Horticultural Society's meeting. Wednesday, October 17: Morley and District Paxton Society's meeting. Friday, October 19: Eastbourne Horticultural Society's meeting. Saturday, October 20: Carnwath Chrysanthemum Society's Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Hot Water Cure for Scale Insects.*—We need not tell gardeners how much they have to fear from the presence of the Scale Insect in their greenhouses. They know it too well, as they also know the difficulty of removing it. The ordinary applications employed to arrest its progress—tobacco-water, sulphur, lime, soft mud, gum, paste, etc.—all are powerless before it: and it was not till Mr. Gordon ascertained that water of the temperature of from 150° to 160° Fahr. would kill the Scale without injuring trees, that gardeners had any chance of even keeping it down, except by a process little less wearisome than his wheel to Ixion. Rub, rub, rub—scrub, scrub, scrub; this was the endless doom of the unlucky labourer until the virtues of hot water were ascertained. In the meanwhile trees perished in gardens, and what was worse, in the colonies. The Orange trees of the Azores were devoured, or rather sucked to death, by the Coccus, and at one time it was feared that it might overwhelm all Orange-growing countries in one common ruin. But although the Scale may certainly be destroyed by hot water wherever it can be brought instantly in contact with it, yet there is a practical difficulty in the application of the remedy in consequence of the smallness of the creature and the facility with which it can screen itself in the crevices of bark or in the earth itself. Vigilance is, therefore, still demanded in order to keep it down, or a sudden multiplication of it may take place to an extent which leaves no remedy except the destruction of the trees and insects by means of fire. *Gard. Chron., October* 7, 1848.

HOLLAND IN AUTUMN.

Seven days do not provide sufficient time for a proper acquaintance with the horticultural features Holland presents in autumn, nevertheless, if the weather be kind, the routes well selected with regard to railway, steamboat and motor transport, and the objectives well chosen, very much of horticultural interest may be seen in such a short period.

The programme arranged on the occasion of the International Horticultural Congress at Amsterdam, as set forth on p. 191, will show that the Congress Committee made arrangements for visitors to see the principal centres of horticultural interest in Holland. From Flushing, through the Westland, a brief view of the fruit-growing district was obtained and large Cherry trees, a goodly number of Plum trees and an abundance of Apple trees were observed, but it was not until towards the end of the time that a better idea of the extent of fruit cultivation in the Westland was obtained. Mr. Hatton, of East Malling, made a special trip to Westland and was delighted with his experience and the observations he was able to make. He found several varieties of Apples not commonly cultivated, some appearing to be new, while certain varieties worked on the Jaune de Metz stock were extraordinarily fruitful and retained their dwarf stature and fruitfulness for many years. But although Mr. Hatton and others admired the skill of the Westland growers, and were full of admiration for their co-operative methods, no one was impressed with the cultivation of Tomatos in Holland, and all were agreed that we grow these better at home.

In every country where fruit is grown extensively the cultivation of certain kinds tends to be centralised in a few places, and probably in no country is commercial fruit production so centralised as in Holland, where the Westland growers have the advantage of the Hook of Holland as a handy port of export for their goods. Not only are Apples grown largely in the Westland district, but Pears, Peaches, Nectarines, netted and Cantaloup Melons are also grown extensively for the home and British markets.

A subject of general comment was the lush greenness of the grass on the Polders and the large numbers of Friesian cattle per acre. Another matter which impressed British visitors was the enormous extent of the cultivation of Sugar Beet, which serves the dual purpose of providing sugar and feeding cattle, as we understand the larger part of the refuse after the manufacture of sugar is returned to the farms and used for cattle feeding.

Of course, to those previously unacquainted with Holland the long lines of Poplars by the canals proved a striking feature, but whether the visitors were making the trip for the first time or not, all were full of admiration for the woodlands around Haarlem and also around The Hague, and for the numerous large private establishments near the latter town, in many of which it was obvious that good gardening is being carried on and tree planting is made a feature.

At The Hague there is an excellent system of public parks and open spaces, and most of the visitors had a special opportunity of briefly inspecting these under the guidance of the Superintendent. It was interesting to observe that The Hague has a public Rose garden which is beautifully kept and in which many popular and some lesser-known varieties of Roses are cultivated in large numbers. This, however, is a new feature of The Hague and will be more worthy of inspection next year.

The visit to Aalsmeer was a great event, for this little town is the centre of the flower producing industry in Holland. Practically every establishment is separated from its neighbour by a canal, and in many cases canals serve the purpose of roads for the conveyance of flowers and other goods. There are three markets at Aalsmeer, two of which concern themselves chiefly with the distribution of flowers and plants. In each of these the produce is disposed by Dutch auction, consequently the business proceeds in a particularly quiet and orderly manner; indeed, the method of sale and distribution is in striking contrast to that which obtains in Covent Garden. The enormous number of Dahlias offered for sale as cut flowers was the subject of general comment. At home we have not come to regard the Dahlia as a serious competitor with the Gladiolus and early-flowering Chrysanthemum as a subject for cutting for the market.

Most readers of *The Gardeners' Chronicle* are aware that at Aalsmeer Lilac is grown and forced on a very extensive scale, and that the majority of the graceful and sweetly-scented sprays which come into England from the middle of December onwards are grown there. Roses are cultivated even more extensively, and we saw houses half an acre in extent in which many thousands of Roses were planted and flowering freely in September. Messrs. Barendsen Bros. have one house covering nearly three-quarters of an acre, containing 25,000 plants. Hadley, Ophelia, Golden Ophelia, Mme. Butterfly, Mme. Abel Chatenay, and Lady Hillingdon were amongst the varieties most extensively grown. As a deep red Rose, the American variety Hadley appears to be grown to the exclusion of all others of its class. A French variety new to us, pink and fawn, and named Aspirant Marcel Rouger, is being grown for market, and is worthy of attention from home growers. *C. H. C.*

(*To be concluded.*)

THE ROSE GARDEN.

ROSE JOAN WADDILOVE.

The new Rose named Joan Waddilove, illustrated in Fig. 79, was prominent amongst the new varieties submitted for award at the autumn Exhibition of the National Rose Society on September 20. It was raised by Messrs. S. McGredy and Son, an Irish firm that has been most successful in raising new Roses, and who gained a Certificate of Merit at the show referred to for another variety named Victor Waddilove.

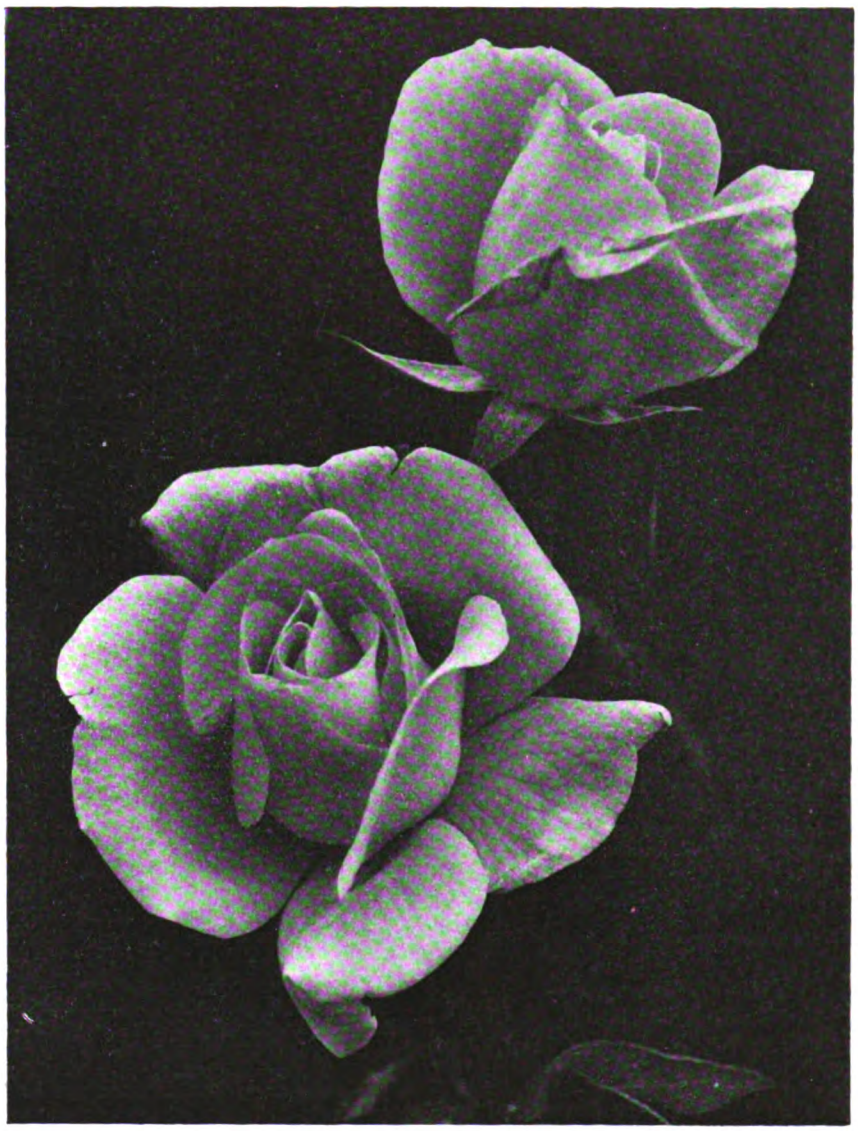

FIG 79.—ROSE JOAN WADDILOVE.

The colours, however, of these two new Roses are quite distinct, for whereas Victor Waddilove is a bright shade of pink, Joan Waddilove has much gold in the petals, the ground colour being slightly flushed with purplish rose-pink; the golden reverse to the petals shows most conspicuously.

As will be seen on reference to the illustration, the bloom is of very pleasing form, and although not suitable for exhibition purposes, this new variety will doubtless make a good garden Rose. The growth of the plant is said to be robust, and, judging by the examples exhibited, this new variety is very free-flowering.

Many of the newer Roses have golden colour associated with other tones, derived in most cases from the influence of the Persian Yellow Rose, Rosa lutea, the gold being usually most pronounced at the bases of the petals. In the variety illustrated, the gold colouring is the chief attraction, and, as stated above, shows prominently on the under sides of the petals.

The Week's Work.

THE ORCHID HOUSES.

By J. T. Barker, late Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

Oncidium.—The recent importations of Oncidiums will enable many to replenish their stocks of these graceful Orchids, of which in most cases there are too few. These imported plants may be potted or placed in baskets or on rafts, according to their respective habits, and treated much in the same manner as the established plants. Many of these Orhids are sending up their flower spikes, and should be grown in a light place and watered carefully until the spikes have developed. Light, more than heat, has a great influence on the development of the flowers, but when the blooms are developed it is not wise to expose them to strong sunlight, especially if it is desired to retain them for a reasonable time. Many Oncidiums, such as O. varicosum Rogersii, O Gardneri, O. crispum, O. ampliatum, O. incurvum, and some of the hybrids develop very large spikes in comparison with their size, and these, if allowed to remain for a considerable time, have a debilitating effect, in many cases resulting in the death of the plants. It is wise, therefore, to remove the flower spikes immediately after the flowers are fully expanded, and especially if the plant shows signs of shrivelling. The flowers of many of the Oncidiums are small individually, but when produced on large, strong spikes, these plants are amongst the most showy and useful Orchids grown With few exceptions Oncidiums require an intermediate house temperature, with a fair amount of sunshine, especially at this season, to ripen the growths as much as possible before the winter, as unless they are well consolidated there is a danger of them decaying.

Oncidium Lanceanum.—This sweetly-scented Orchid is sending up its flower spikes, and should be given plenty of water until the new leaves and flower spikes are fully developed, and then kept fairly dry until growth commences again in the spring. This large, terete-leaved Oncidium, with others of a similar nature, is capable of withstanding a considerable amount of drought, and is the better for a good rest if drying off is not done too drastically.

Oncidium Cavendishianum and O. carthaginense.—These two terete-leaved varieties are like O. Lanceanum in growth, and should also be grown in the stove, and given plenty of water until the new leaves are fully developed. These are now in full growth, and should be well exposed to the light in order that the growth may be thoroughly ripened. Large, soft growths of these plants do not always produce the best flowers, and are in some cases not capable of withstanding the vicissitudes of the winter.

HARDY FRUIT GARDEN.

By A. J. Hartless, Gardener to Major J. F. Harrison, King's Walden Bury, Hitchin, Hertfordshire.

Harvesting the Fruit Crop.—Ripening fruit will require daily attention. Where large quantities of Apples are growing it is desirable to apportion the fruit store into sections, which may extend to four in dessert kinds. The general way is to divide the sorts of both culinary and dessert into three, namely, early, mid-season, and late. Fruit arranged in this way is easily accessible.

The Colouring of Fruit.—Apples, and particularly the varieties James Grieve and Allington Pippin, have developed very high colouring this season; Cox's Orange Pippin, too, has a less russeted skin, which enhances the colour. To obtain a good finish to their fruits is the aim of most growers, and to this end, the necessary ingredients to the soil in which the trees are growing should be supplied. The amount of potash and phosphates required varies, but a liberal quantity of lime, in the form of lime rubble, is more particularly desired each year by stone fruits. The roots, too, should also be near the surface, for trees with roots that are deeply buried are not likely to produce fruits of high colour. Summer pruning is also an aid in the production of good-coloured fruit. Outside Peaches, on the contrary, are not, at any rate with us, colouring or keeping so well as usual this season. Nothing is more pleasing than to see an evenly balanced fruit pergola, with its varied colouring of fruit and autumn-tinted leaves. The aim should be, if this effect is desired, to have varieties with fruits maturing at the same time. For this purpose varieties which will be at their best in the early part of October would probably find most favour.

Autumn-fruiting Raspberries.—One of the best of autumn-fruiting varieties is Lloyd George, introduced by Mr. Kettle, of Corfe Castle. It is equally good for summer cropping. This Raspberry produces fine canes and fruit of good size, and in large quantities. The extension of the season of bush fruits is welcomed, and the introduction of a late Black Currant, September Black, by Messrs. Daniels, is another step in this direction.

Wall Trees.—One is often asked what trees are suited for certain aspects. For south and west walls the same kinds are, for the most part, suitable, and include Apricots, Peaches, Nectarines, Plums and late Pears. For east walls Plums, Cherries and Pears may be selected, and trained Gooseberries and Currants for north walls, with Plums, Morello Cherries, Early Pears and Sweet Cherries for succession. Late fruits of Currants and Gooseberries may also be obtained from bushes on north walls. White Currants especially keep well in this aspect. Figs or Grapes need to be grown on sunny south walls. A few of the less hardy Peaches should have a south aspect. Blackberries have bore freely this year, especially the American variety. With a lean fruit year, and soft fruit deteriorating rapidly after picking, the fruit grower has had a bad time.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Fuchsias.—Large specimen Fuchsias from which water has been withheld gradually may be stored for the winter in a frost-proof shed. Young plants rooted last month should be kept growing steadily all through the winter, allowing the leading shoot to grow without stopping it; as most varieties throw out lateral shoots naturally the latter should be pinched frequently to obtain shapely specimens.

Crinum Powellii and C. Powellii album.—Where grown in tubs for conservatory decoration these bulbous plants may be stored in a frost-proof shed. Agapanthuses may be stored in the same way; but, if room can be spared, these plants do better in a cool greenhouse.

Wintering Tender Plants.—Tuberous-rooted Begonias should, when they are dried off, be stored in a cool, dry shed free from frost. Gloxinias, Achimenes, Caladiums and Gloriosas require warmer conditions to bring them safely through the winter. They may be stored in their pots, or, if space is a consideration, should be shaken out and stored in boxes or pots of dry sand.

Phyllanthus pulcher.—This very graceful stove plant, grown in 48-sized pots, is ideal for table decoration. It may be propagated at any time during the spring and summer, inserting the cuttings in pots of sandy soil, and plunging them in a warm propagating case. P. nivosus is another beautiful species, which used to be a favourite decorative plant; it is a slender, freely branching shrub, and is easily propagated by means of cuttings, placed in a warm propagating case. Half-ripened wood should be used for cuttings. Its successful cultivation presents no difficulty, as it grows in any good potting compost. P. atro-purpureus is a somewhat stronger growing species, with dark purple foliage. All the Phyllanthuses require stove treatment.

THE KITCHEN GARDEN.

By R. W. Thatcher, Gardener to Mark Firth, Esq., Carlton Park, Market Harborough, Leicestershire.

Parsley.—Plants of Parsley raised from seed sown last month should be ready for pricking out into cold frames about 4 inches apart. They should make good progress, and provide young leaves for use in winter and early spring. Keep the soil well stirred between the plants, and dust the rows occasionally with old soot. This will keep slugs away, and also act as a stimulant. Water the plants while the weather is bright, but later water should be applied only when the soil is dry.

Turnips.—When the Turnip crops are mature the roots should be lifted and stored in sand for winter use, after cutting the tops off fairly close to the roots. Those still growing actively should be kept well hoed, and a little soil drawn up to them to protect them from frosts.

Chicory.—Roots of this useful salad plant may now be dug up and placed in boxes or pots of soil after first trimming off the tops closely. The boxes should be placed in a Mushroom house or a dark shed. The plants will soon send up new leaves. They should not be forced too hard. Where plenty of Lettuces and Endives are available there will not be much demand for Chicory yet, therefore it is advisable not to dig up too many roots at one time.

Parsnips.—It is generally agreed that Parsnips are improved in flavour after frost, but they may be used now if required. The roots are much better left in the ground and dug as required, but in the event of severe weather it is wise to dig a supply and store the roots in sand.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to J. A. Bennett, Esq., Woolverstone Park Gardens, Ipswich.

Late Peach House.—Any shading material on the roof-glass should be removed, as the maximum amount of sunlight is necessary to thoroughly ripen the wood. The ventilators should be left fully open night and day, and the trees be well syringed every afternoon until the foliage is matured. If the borders are dry give them a good soaking of water forthwith, using clear lime-water.

Fruit Trees in Pots.—The time is at hand when pot Fig trees should be removed from the orchard house to the plunging ground, and the opportunity should be taken of repotting such plants as require this attention. Any trees that require larger receptacles should be repotted, if possible, before the foliage has fallen entirely. The roots of each tree should be examined, and treatment afforded according to its condition. If the roots are much matted together, shift the plants into a receptacle one size larger than it has previously occupied, first disentangling the roots on the outside of the ball. It may be necessary to replace the plant in a pot of the same size, and, if so, with the aid of a pointed stick loosen the ball of roots in order that some of the old soil and the whole of the crocks may be shaken away from the roots to allow room for fresh drainage and fresh soil. Should the soil be exhausted or in poor condition, remove as much of it as possible; if the roots are in a bad condition repot the tree in a pot of smaller size. In many cases it is not necessary to disturb the roots, a top dressing sufficing for another season. In applying this, remove as much as possible of the surface soil by means of a pointed stick, and make the fresh material quite firm with a rammer. Allow room in the pot for watering. The pots selected for use should be perfectly sound, otherwise, sooner or later, trouble will occur, usually when the trees are rooting freely, and require an abundance of water. The crocks should be carefully arranged to ensure good drainage, and over these should be placed a layer of turfy fibre. Good loam of a rough, friable nature, with a liberal addition of broken plaster or old mortar rubble, and a 7-inch potful of bonemeal to each barrowload of soil, should be used for

Digitized by Google

potting purposes. When repotting is finished remove the trees to the plunging ground, and sink the pots to their rims. Coal ash is to be preferred for plunging purposes, as this material is free from worms, and permits of water draining away from the pots freely. If the pots are plunged in soil a certain amount of hard material should be placed immediately under each pot to ensure free drainage, and sprinkled with soot to prevent worms entering the pots. Some of the trees may require a support for a time after they are potted, otherwise they will be liable to be disturbed in their pots during very rough weather.

THE FLOWER GARDEN.

By C. Turner, Gardener to Emily, Lady Ampthill, Ampthill Park, Ampthill, Bedfordshire.

Preparations for Rose Planting.—Where new Rose beds are to be made, or existing beds taken up and replanted, the ground should be prepared in advance of planting to allow of a reasonable time for the soil to settle in position. A strong loam is the best rooting medium for Roses, and needs no other addition beyond a sprinkling of ½-inch bones incorporated with the top layer of soil. Poor soil should be enriched with well rotted farmyard manure, and should be so placed that the roots do not come in contact with it for the first year—the plants having no use for manure until they are established. A little bone-meal may be added to this latter type of soil at planting time. Plants lifted from beds that are to be overhauled and replanted should be laid in carefully elsewhere until wanted.

Herbaceous Phlox.—Autumn cuttings of perennial Phloxes are not always to be had—many stools seeming to lie dormant after flowering—but if they can be obtained and are wanted, the resulting plants will be stronger and flower earlier than those raised from cuttings inserted in the spring. Dibble the cuttings in pots of sandy soil, and plunge the pots in a cold frame that can be made frost proof. Although there are plenty of excellent varieties in commerce the raising of a few seedlings is interesting. Gather the seeds as soon as they are ripe and press each one separately into a pan of sandy soil, which should be placed on a greenhouse shelf until the seeds have germinated. The seedlings should be pricked out when large enough and hardened gradually.

CULTURAL MEMORANDA.

PRUNUS TRILOBA.

This species is one of the best members of the Prunus family for forcing, and lends itself to many uses, not the least among them being its value as a cut flower for vase decoration.

Young plants should be procured as soon as possible, potted in a suitable mixture when received and stood in a sheltered spot out-of-doors.

Any time after the New Year is early enough to commence forcing them, and, as in the case of all shrubs that are forced, they should be taken into an intermediate house for a week or so before being introduced to the forcing house. A temperature of 65° is suitable—in a higher temperature the plant will not give of its best. and constant syringing is necessary until the flower buds begin to open. It is well then to cool the plants down at this stage, and if this is done carefully the flowers will remain for three weeks or a month in perfection.

After flowering it is well to encourage the development of growth by placing the plants in a warm Peach house, when, after the severest frosts are over, they may be placed out-of-doors in a sheltered situation. If they are to be retained for forcing the following year they should be trained carefully, removing all unnecessary old wood immediately after flowering; giving the roots some slight stimulant during the summer. Planted outside in a shrubbery this Prunus is of great value—both for its hardiness and its wealth of double pink flowers in April.

DICENTRA SPECTABILIS.

If clumps of this charming plant are potted during October and kept in cold frames, they may be transferred in batches to a warm house during January as required. Gentle forcing and plenty of light, with frequent syringings, are practically their only requirements, and they are not fastidious in regard to soil. Dicentras are very charming associated with forced Narcissi, and they have the advantage of possessing pleasing foliage. If aphis should attack the plants when they are growing actively, syringe them with weak quassia, fumigating being apt to "burn" the edges of the leaves—while, if in flower, the erstwhile pink of the beautiful blossoms will turn to a sickly grey and spoil the effect. A better-known generic title for this plant is Dielytra.

COREOPSIS GRANDIFLORA.

Sow a few seeds of this annual now in a cool house. When they are large enough, prick off the seedlings into small pots of loamy soil, and grow the plants on a shelf in any airy house until they are well rooted. They may then be transferred to 48-sized pots, and, if grown hard in a cold house, will give a welcome bunch of cut flowers in the spring, or, if carefully staked, will make quite goodly shaped pot plants.

MUSCARI IN POTS.

These lovely plants, grown in pots, provide a pleasant change from the ordinary series of forced bulbs, and the blue colour strikes a note of contrast to the yellow Daffodils, An ordinary potting compost will suit them, and they should not be planted deeply, but placed firmly in a cold frame facing north. Do not cover the pots with ashes, but keep the frame dark. When growth commences, allow the plants all the light and air possible, a shelf in a cool house being an ideal place on which to grow them. Gentle warmth may be used in the house from the middle of January, but the plants need to be kept close to the roof-glass, or the flower stems will "draw" and become useless. Before the buds open, remove the plants to a cooler house and allow the blooms to develop slowly. The best Muscari for forcing are Heavenly Blue and botryoides. *J. D.*

BROMPTON PARK NURSERY.

THIS one-time famous London establishment derived its name from an old country residence, the site of the nursery being on part of the park belonging thereto. Over 100 acres in extent, it lay between Old Brompton Road and Kensington Road, and it was bounded on one side by the present Gloucester Road. From the very beginning its history and that of its numerous owners is obscure. Not for lack of notes, but because these disagree. We cannot always be certain who were its owners at different periods, nor even be sure when and to whom it passed during the years of its existence till at last its greatly diminished space was acquired by the Royal Commissioners of the Great Exhibition of 1851 for the site of the South Kensington Museum.

In the *Gardeners' Chronicle* for March 19, 1892, and September 13, 1913, are articles on London and Wise, the most famous of its early proprietors, in which occur remarks that need not be repeated here. But there may be some that need correction. There is, for instance, the date of London's death, which is almost always recorded as 1717. But Switzer's statement that it was at the end of 1713 is corroborated by Laurence in the preface to *The Clergyman's Recreation*, in which, referring to London and Wise, the former is mentioned as "the late." This was in March, 1713, and seemingly contradictory to Switzer, but as that date is now equivalent to 1714, it is clear that Switzer was correct. Other dates about which there is diversity are those of the death of the two senior partners of the original association, the retirement of Cook and the admission of Wise to partnership. Usually, the date given of the first-named change is 1694, but in an unsigned article, obviously by Dr. Hogg, who became a partner in the business 81 years ago, 1686 is recorded as "about the year"; and 1689 as that in which Cook retired, in which year he disposed of his share in the business to Henry Wise, and in 1690 the association of London and Wise was begun.

It is possible, but improbable, that Dr. Hogg may have been mistaken. There is no certain record of the retirement of Wise, who must have lived to a very advanced age, for Horace Walpole, in one of his gossipy letters, mentions having met him. One writer states that Joseph Carpenter, who edited the second edition of *The Retir'd Gardener* in 1717, was associated with Wise until several years later. Loudon, on the other hand, in more than one instance states that Swinhoe, Smith and Co. succeeded London and Wise, while Dr. Hogg disagrees with both, and writes: "In the year 1714 the nursery passed into the hands of Smith and Carpenter." These were succeeded by Swinhoe, who retired in 1755-1756. One thing is clear, that the establishment had lost its unique position previous to the appearance of Miller's first book in 1724. For none of these names is to be found in the list of leading nurserymen and florists of that date, nor do we hear of them elsewhere. Mr. Jeffreys, a relative of Swinhoe, carried on the business till 1788, when he was joined by Mr. James Gray, its title being for a brief period Jeffreys and Gray, but the first named died shortly after completion of the partnership. A nephew of Jeffreys' named Wear succeeded to the latter's share in 1790, and a little later a brother of Gray's entered the business, on which the firm became Gray, Wear and Gray, which continued till 1809, when Wear retired and the original Gray followed in 1818, a nephew succeeding him, when the firm became James Gray and Son.

In 1827, Robert Brown, a Scotsman, was made a partner, but he died young, and his place was taken by Adams in 1837, the firm being then Gray, Son and Adams. In 1842 the Gray who entered the firm in 1818 died, when Robert Hogg—of whom more below—entered it, though I have seen 1845 given as the date of his entry, the title henceforward being Gray, Adams and Hogg. The first named retired in 1847, then 87 years of age, and Hogg followed in 1848, the business becoming extinct in 1850 or 1851.

It is worth noting that the firm's early years were noteworthy for a personality of outstanding distinction in George London; and in its latest by a personality of equal distinction, though of a different nature, in Robert Hogg, better known as Dr. Hogg, concerning whom a few remarks may be of interest to the generation that has arisen since his death. He was born in 1818, the son of Robert Hogg, farmer and nurseryman, near Duns, Berwickshire, the latter being head of the still vigorous firm of Hogg and Wood, of Coldstream and Duns. The youth left Edinburgh University for London in 1836, and started work in Ronalds' Nursery, at Brentford, but left there shortly afterwards, and seems to have been very unsettled for some years. He had a weakness for old books, and even when in Edinburgh commenced gathering together a library of works, ancient and modern, on gardening and allied pursuits, which sold subsequently to his death for over £3,000. He also early took up the study of hardy fruits, not only their nomenclature, as some might suppose, but also their cultivation. It is significant that Gray, Adam and Hogg published a descriptive catalogue of fruits in 1847, entitled *A Manual of Fruits*, and this was probably the germ of the *Fruit Manual*, though what may be termed the first edition of that standard work on pomology came out in parts at 1s. 6d. each in 1851 and 1852. It is entitled, *British Pomology, or the History, Description, Classification and Synonymes of the Fruits and Fruit Trees of Great Britain*. And here may be interpolated a note on how difficult it is to be certain of dates. In this work it is stated that 2,500 Ribston Pippins were "now" worked in Brompton Park Nursery, which would prove conclusively that that establishment was still a going concern. But on reference to the *Fruit Manual* the "now" is elided and "in 1847" substituted. At the time of Dr. Hogg's death in 1897, material for a new edition of the last-named book had been prepared. I have a suspicion that he was responsible also for a small volume on *Fruit Trees and Fruit Bearing Shrubs*, which was published anonymously. He wrote a monograph on the *Dahlia* in 1853, and brought out the *Herefordshire Pomona* in conjunction with Dr. Bull, as also an illustrated *Flora* embodying the results of much research. About the time of his retiral from Brompton Park, Dr. Hogg established a private orchard at Worth, Sussex, for the purpose of observing the characteristics of hardy fruits.

In 1851 Hogg wrote a note to *The Cottage Gardener* to rectify a mistake made by its editor, Mr. G. W. Johnson, better known, perhaps, as the author of *A History of English Gardening*, which led to a long friendship, their tastes in many respects being similar. One result was that he became a constant contributor to that journal; in 1855 became joint editor and proprietor, and on the retiral of Mr. Johnson in 1879, sole proprietor. Long before this its title had been changed to *The Journal of Horticulture*. When at Brompton Park he discovered a large number of letters stowed away as lumber in a box in the office, which proved to be the correspondence of W. Forsyth, gardener to the King at Kensington, and a well-known personage and author. Forsyth succeeded Miller in the superintendence of Chelsea Botanic Garden. A selection of these letters was published by Mr. Johnson, some of them being of much interest, and of these one or two may be noted here. One from the Prime Minister of the day, with the reply, throws a vivid light on the gardening of the period as it affected gardeners. The Minister had sent his gardener to Forsyth, obviously to receive instruction, and wrote to the latter complaining of the treatment he received being no better than that accorded to a common labourer. To which Forsyth explained that there was only a greenhouse and some structures for forcing Strawberries under his charge, and that he could give as wages only 10s. 6d. per week in winter and 13s. in summer. Other letters relate to the initiation of the Royal Horticultural Society, which was first mooted by a son of Wedgwood, the great potter. He had also correspondents abroad who sent home seeds and plants of novelties they discovered.

Of the first Robert Hogg, I believe there is now no representative in the male line. It would be a serious omission not to state that Dr. Hogg was a Tulip enthusiast from his youth up. *R. P. Brotherston.*

IRISES.

IRIS PUMILA.

WHILE the larger Bearded or Flag Irises undoubtedly have the premier value for inclusion in gardens, the smaller species and varieties of similar, though less imposing, attractions are eminently suited for certain positions. None of these smaller Bearded Irises is more delightful than Iris pumila and its varieties, which are not too often cultivated, their places being frequently taken by hybrids, which, though taller, are by no means so delightful for the rock garden, for which the pumila varieties are so charming; nor can they even rival them in contending for a place near the front of the border devoted to Irises or a mixed collection of herbaceous plants. They are, indeed, delightful little plants, natives of South Europe and Asia Minor, but hardy and free, as a rule, from any objection to our climate. They may be successfully cultivated in common soil, preferably in a sunny place. Planting in July or March is recommended, the former month being generally favoured by the best growers. The true I. pumila is only about 5 or 6 inches high, whereas the hybrids often sold for it are considerably taller, coming in midway between I. pumila and the larger Bearded Irises.

These Irises flower about April and have wonderfully large blooms, possessing the beard which characterises the larger Bearded Fleur de Lis. There are not so many varieties as in the hybrid class, but the following are all of much beauty and fitting ornaments for a choice rock garden or border.

The type has violet or lilac purple blooms, the standards lighter in colour than the falls, which are ornamented by a large white beard. Alba is a pretty white variety, but not absolutely pure, as it possesses a blue blotch; atroviolacea is a deep purple-violet variety with a blue beard.

In azurea or coelestis we have a pretty variety of a charming shade of azure blue. Gracilis or cinerea is of a greyish white with bronze falls, while lutea is yellow, and macrocarpa of a bluish violet. *S. Arnott.*

PLANTS NEW OR NOTEWORTHY.

NOTES ON EAST AFRICAN PLANTS.

(*Concluded from p.* 205.)

In the background of Fig. 80 is depicted a species of Carduus, of which there are 22 species in East Africa, as lately revised by Dr. R. E. Fries (*Act. Hort. Berg.*, 8, 11, 1923). In the foreground are fine examples of Delphinium candidum, one of the very few examples of this typically boreal genus which occur south of the Equator. Huth, in his monograph of the genus Delphinium, has remarked on the peculiar structure and isolated position of the only two other species, D. macrocentrum and D. Leroyi, which reach the Southern hemisphere. Such characteristics seem to point to these representatives of northern genera being not merely outliers, but definite relics of a former and much more widely spread temperate flora peculiar to the Southern Hemisphere.

A fine illustration of the weird forests of giant Lobelia (L. Wollastonii) and Senecio (S. Johnstonii) is given in Fig. 81; both species are named after well-known and intrepid explorers of Tropical Africa. The photograph was taken by Mr. Barns, on the Ruwenzori Mountains, between 12,000 and 13,000 feet, just below the snow line. These giant species tower above a ground vegetation of Ericaceae (Blaeria?), Alchemilla cinerea, and species of Helichrysum.

Mr. Barns describes the plant seen in Fig. 82 as a "giant aerial bulb," and it is, I think, an example of Adenia globosa (Passifloraceae), which is unique in the genus on account of its peculiar habit. The swollen base is evidently a nesting place for ants, which, together with the prickly branches, no doubt form a formidable protection against the ravages of animals. *J. Hutchinson, Kew.*

RUBUS MESOGAEUS.

In *Trees and Shrubs Hardy in the British Isles*, a fine selection of decorative brambles or Rubus is given. To this list I would like to see added another species worthy to be cultivated for its general appearance, notably as a distinctive and attractive foliage plant, namely Rubus mesogaeus, Foche. It is a native of Western Hupeh and Western Szech'uan, and was first described by Foche in 1901. Later on, in 1907, it was collected by Mr. E. H. Wilson, in thickets near Tchang, etc., at an altitude varying from 1800-3600 feet, and from his collection numbers 52a and 71, the plants grown at the New York State Agricultural Experiment Station are derived.

Although the plants are killed back to the ground every winter, they come up vigorously in spring, and during summer form large, round bushes about 2½ to 3 yards high, with stems about 1 inch thick and copiously branched, carrying most attractive foliage. These stems or canes are greyish-green, with a light red tinge on the exposed side, and densely covered by a thick felt of long greyish hairs and numerous hooked prickles, which are curved upwards. The leaves are trifoliate on rather short, felty and prickly stalks, and doubly or almost lobately toothed. The terminal leaflets are much larger than the lateral ones, so much as 6 in. long and 5 in. wide. They are softly hairy above and covered with a dense white felt beneath, and thus soft to touch, but the midrib and lower lateral veins are prickly.

The hairy tomentum of the canes is so strong, that it extends to the prickles, which are beset almost to their point with spreading hairs. The stipules are strangely fissured into several subulate points.

As the canes of this remarkable Chinese Raspberry do not survive our winters, I have not been able to see either flowers or fruits. The flowers are white and probably not very showy; but there is a variety with rose-coloured flowers, which may be hardier as, according to Mr. E. H. Wilson, it grows at almost 10,000 feet elevation in woodlands west of Kuan Hsien.

The fruits are said to be small and probably are of no value from a pomological point of view.

In regions with milder winters than ours (Geneva, N.Y.), this Raspberry will no doubt prove to be a very ornamental plant; it is certainly one of the finest species of Rubus ever introduced. *Alwin Berger.*

FIG. 81.—A SCENE ON THE RUWENZORI MOUNTAINS, SHOWING A FOREST OF LOBELIA WOLLASTONII, SENECIO JOHNSTONII, WITH A GROUNDWORK OF ALCHEMILLA CINEREA, ERICAS AND EVERLASTING FLOWERS.

ERICA VAGANS VAR. ST. KEVERNE.

This form of the Cornish Heath is one of the most striking and valuable additions that have been made to our garden Ericas for some years. It has a free, yet compact, habit of growth with foliage akin to that of the type, though perhaps somewhat darker in the green than that of most varieties. The flower spikes, as well as the individual blossoms, are unusually large and showy, and the colour is a soft, salmony rose, quite distinct from that of any other variety. E. v. St. Keverne will doubtless soon become one of the most popular of its class for grouping in large beds, for bold edgings and massing with other Heaths in open woodland or the wild garden. *A. T. J.*

TREES AND SHRUBS.

AUTUMN-FLOWERING HEATHS.

Although the flowering date of most Heaths varies considerably in accordance with local conditions, there are some which may usually be expected to be at their best during September and throughout the autumn. Even Daboecia polifolia, which frequently breaks into colour at the end of May, often keeps its good wine until the end, giving us a crop of blossom in autumn which is finer than that of earlier days. This is especially true of the splendid white form.

Then there is Erica ciliaris which, though certainly later to come into flower than the above, does not display its fullest beauty in North Wales until most of its summer rivals are well out of the running. Though perhaps the most tender of our native Heaths, E. ciliaris is such a charming species, with its soft green, downy mats of semi-prostrate foliage and splendid, erect racemes of rosy-purple flowers which are borne well into November, that it fully deserves any little protection that the climate may render necessary.

The lovely pure white variety of E. ciliaris is a gem, not to be outshone by any contemporary, and another very beautiful form of this species is the variety Maweana, which also flowers late. This form was discovered in Portugal about fifty years ago by Mr. George Maw, and although it bears all the characteristic features of the type the blossoms are even larger and the foliage, perhaps, a trifle darker and inclined to be more upright. E. Watsonii, a natural ciliaris × tetralix hybrid, also comes into this set, and it is quite distinct in its dense, emerald-green foliage and short, blunt heads of rose-purple blooms.

E. Mackayi, whilst bearing no little affinity with Erica ciliaris in its sprawling habit and other respects, also suggests a strong infusion of tetralix parentage. Thus, while some authorities claim it to be no more than a form of the last-mentioned, others hold it to be another ciliaris × tetralix hybrid. However, E. Mackayi, which comes from that home of many quaint things, the West of Ireland, is an excellent low-growing Heath with rather rounded bells in a clear, yet full-toned, rose-pink. The flowering season extends from about the middle of August well into autumn, the very attractive double variety holding out the longer.

Erica vagans (Cornish Heath) though it may often be in flower during the late summer is usually considered among the autumn blossomers, since its 4-6 in. racemes, which open at the base upwards, will not have spent the last of their blossoms until November is approaching. This loose-habited, but graceful and spreading shrub is generally well enough known and appreciated as a free and easy doer as well as a prolific bloomer. In addition to the typical form, which is a purplish-pink, there are varieties in white, cream, crimson and other shades. But the Cornish Heath which is most likely to win the greatest esteem in the near future is the comparatively new variety, St. Keverne (see p. 219), whose very large blooms are a beautiful salmony rose.

E. vagans makes a useful edging, or low hedge about 2 ft. high, and it is particularly valuable for this purpose inasmuch as it stands the shears better than most. This clipping over—just enough to keep the bushes or edging in shape—should be carried out in spring and the effect is not only greater neatness but more and better blossoms. Another admirable Heath for such purposes as the above is E. stricta (corsica) which will, in favoured spots, ultimately attain the height of 5-6 feet. But this handsome species is naturally compact and orderly in shape and only needs occasional pruning. The habit is somewhat stiff and upright, and the fresh, moss-green foliage has an uncommon, bristly appearance owing to the leaves being set in whorls. The flowers, which appear during September in terminal umbels, are a vivid rosy-pink and the faded corollas, which turn a rusty-red, are by no means unattractive in the winter garden. E. stricta is quite hardy in all save our bleakest counties and it is a species that merits a much wider appreciation than it now enjoys.

Among the latest of the Callunas to bloom here are C. Alportii, with very dark green foliage and rich crimson flowers, the varieties aurea and cuprea, usually being grown for their foliage; and the dwarf, moss-like Foxii. The very beautiful double-flowered form of the type, C. vulgaris flore pleno, naturally last longer than the single, and in the whites C. v. Hammondii usually precedes the more elegant Serlei. But in all of these and others the date and extent of the flowering period are governed very largely by the soil and weather conditions, and young, vigorous plants will usually bloom earlier than old-established clumps. *A. T. Johnson, N. Wales.*

CHOISYA TERNATA.

The Mexican Orange Blossom, although usually seen growing against a wall, may be planted in the shrubbery. Its dark green, glossy foliage is very fine, and when in flower with its large clusters of creamy-white blossoms the plant is a conspicuous object. It is fairly hardy, but it is advisable to give the plant a little protection from sharp frosts. It should be planted in a warm, sunny position in order that the wood may become well ripened, and as it makes dense growth, should be protected against damage by heavy snow, the weight of which might cause the branches to snap off.

This Choisya flowers in May and June and occasionally again in the autumn, and the blooms are very fragrant. It will also thrive well under trees, provided they are not too dense and the soil is good. *T.*

VIBURNUM TOMENTOSUM.

It is not always the most strikingly brilliant coloured foliage that proves the most effective, and this idea was impressed firmly on my mind when looking at a large bush of Viburnum tomentosum a few days ago. The wonderfully artistic colouring is superb. Usually one regards this plant as a flowering shrub only, and certainly as such it is of the very highest merit, but one must also admit it holds a high position for the colouring of its foliage, which ranges from the deepest coppery red on the older leaf surfaces through lighter shades of red and deep pink to the younger leaves that are of pretty light, bronzy green flushed with deep pink markings according to age. The stem and growths are bronzy brown, whilst the leaf-stalks are very deep red, and then, to finish off, there is the paler under surface suffused with pink. The whole is marvellously toned down by the leaf tomentum. The variety V. tomentosum plicatum is almost as beautiful, but the leaves are of somewhat smaller size. *E. Beckett.*

SPIRAEA JAPONICA.

The type species of the group of shrubby Spiraeas included under the above term is not so well known, nor is it so attractive as some of its varieties. The most popular of the latter is Anthony Waterer, a sub-variety of S. j. var. Bumalda, one of the handsomest of its race, and especially valuable on account of its late flowering. The broad, crimson-carmine corymbs of this shrub, much more brilliant than those of the dwarfer Bumalda, are well known, and this season they happen to be especially good. This is due not only to the abundant rains of the later summer, but also to the fact that there has not been sufficient sun to bleach the rich colour of the flowers.

One of the most charming varieties of S. japonica is S. j. alba, or, as it is sometimes called, S. callosa alba. This is a very distinct little shrub—so distinct, indeed, that some class it as a separate species. It does not exceed about a foot in height, and the many slender, upright branches, with their pale, almost emerald, green leaves, bear a profusion of white flowers in terminal corymbs. S. callosa alba blooms freely and late, it is perfectly hardy, and easily satisfied as to soil and situation. *A.*

HARDY FLOWER BORDER.

THE SNOWDROP ANEMONE.

Anemone sylvestris, known popularly as the Snowdrop Anemone, is a charming plant where it does well. In some places it thrives so luxuriantly that it spreads freely about a bed or other position in the enclosed or wild garden, but in some other places does not condescend to live for many years. I cannot profess to have solved the mystery of this. The ways of plants are not always easy to learn, and I must confess to being unable to offer any solution of the question as to how to grow Anemone sylvestris. I can only say that I have seen it do best in a somewhat light soil with a good deal of peat in it, and with a fair amount of moisture below, though not in a boggy condition. It is a woodland plant, and a certain amount of moisture appears to be essential to its welfare. A well-known authority recommends for it a light, moist loam, but I consider it does best with a little peat or leaf-soil in the compost. It is a charming plant with pure white flowers borne gracefully on slender stems. Some three varieties are offered by the trade. These are grandiflora, a large-flowered variety of much beauty; Spring Charm, a distinct variety with bell-shaped flowers of large size; and flore pleno, a double one which I do not much care for, but which has been a good deal admired, and which attracted a good deal of notice when first exhibited in London many years ago. Such a lovely Windflower as Anemone sylvestris should be borne in mind when ordering additional flowers for the garden. *S. Arnott.*

CIMICIFUGA.

Cimicifuga, belonging to the Crowfoot family, was introduced during the 18th century. The species are natives of N. America and China. Their foliage much resembles that of the Astilbes, but is of firmer texture and sets off to advantage the many stately spikes rising from 3 feet to 4 feet high. The inflorescence is silvery white, elongated and elegant. From July to October the Cimicifugas are splendid associates for Gladiolus gandavensis, Kniphofias and Campanula persicifolia. All are perfectly hardy, and are readily propagated by division of the roots during the autumn or early spring, and succeed in ordinary, well-drained, moderately enriched soil, in partial shade or full sun.

The following are all worthy of cultivation:—C. acerina, with neat, bright green, Spiraea-like foliage, and pretty creamy-white flowers, borne on 2½ feet branching stems in late summer and early autumn. C. cordifolia, a North American species, with tall and erect, slender, black stems from 3 feet to 4 feet high, supporting dainty feathery-white flowers during August to October. C. dahurica, a pretty Chinese species, with distinct, large glistening foliage, and long branching racemes of pure white flowers, July to September, 3 feet. C. japonica, a distinct and handsome foliage plant, with black, shining, cylindrical stems, and racemes of dainty white flowers; August to October, 3 feet tall. C. racemosa, one of the most beautiful of the American species, and which should be included in all collections of hardy, herbaceous plants, the elegant Fern-like foliage and peculiar twisted drooping racemes of feathery snow-white flowers providing a most charming effect during July to August; 3 feet to 4 feet tall. C. simplex, a lovely, rare Japanese species, bears dense racemes of beautiful snowy-white flowers on erect pyramidal stems, 3 feet tall, during August and September. *W. Logan.*

CHRYSANTHEMUM ROI DES BLANCS.

For garden embellishment, and also as a cut flower, this variety stands out pre-eminently. It flowers over a long period. I have plants in my garden carrying ten to fifteen beautiful white blossoms of Japanese form. This variety does not require pinching; at least I have found it best to allow it to grow at will. Roi des Blancs requires good cultivation, and will be improved in growth and flower if weak manure water is applied to the roots occasionally. *G. L.*

THE DEVELOPMENT OF THE DAHLIA.*

(*Continued from page* 204.)

Dahlia raising and growing was a profitable business. Retail prices for new varieties varied from 10s. to £5 each, and the entire stock of certain novelties was often sold for £100 to £200. Girling, who started as a small grower in 1820, died twenty-five years later, a wealthy man, leaving a capital of over £100,000.

The Dahlia had now become such an important florist's flower, that the inevitable standard for the official qualities of the Dahlia was established. William Smith, in his article quoted already, decrees: "The flower should be fully double, always filling the centre; the florets should be entire or nearly so, pointed or rounded, reflexed, and so forming a globular head, regular in their disposition, each series overlapping the other backwards; they may be either plain or quilled, but never distorted; if, instead of being reflexed, the florets are recurved, the flower will be equally symmetrical."

It is remarkable that "pointed" florets were allowed, which was not so in a later period, when the well-known Glenny drew up the standards for all sorts of florist's flowers. One of the foremost Dahlias was Well's Sunflower, from which the German seedling Neuer Deutscher Kaiser was raised. A coloured plate of the latter is given in the ninth volume of the *Annalen der Blumisterei*, showing a pointed petalled flower of golden yellow colour, with regular vermilion edges. The figure reminds one of another old Dahlia, known as picta formosissima, offered in Dennis's catalogue of 1834, and which reappeared in the early days of the Cactus Dahlias, about 1885.

Another type, which had made its appearance before 1830, was the Anemone-flowered Dahlia the flowers of which have a centre composed of narrow, radiating florets, like the small petals in the centre of a double Anemone; a variety called Painted Lady, figured in Sweet's *Florist's Guide*, was raised from seed by Drummond, from whom the stock was purchased by Lee, of Hammersmith. In our days a similar type has been offered from France, but it has not become generally popular.

The number of varieties raised from seed had soon enormously increased. The *Bon Jardinier* of 1828 described 115 double forms, and at the same time a similar number of varieties was known respectively in England, Holland and Germany. Three years later, the Swiss amateur, Walner, who collected all Dahlias he could purchase from every country, possessed a collection of 1,500 varieties, and in 1841 Harrison tells us in his *Floricultural Cabinet* that the list of his own varieties at that time was 1,212, all double, which he believed to be considerably more extensive than any other.

The superiority of the British Dahlias was generally recognised on the Continent during the period from about 1826 to 1840, but meanwhile the ever-increasing popularity of the Dahlia, which was then considered to rank next to the Rose, as a garden flower, led to the intensive raising of new varieties on the Continent, and between 1840 and 1870 considerable numbers of varieties that competed favourably with the English varieties were put on the market.

In Germany the watering place named Köstritz, in Thüringen, became the centre of Dahlia culture. Both Christian Deegen and Johann Sieckmann started there in 1824 and 1826, and their Dahlias kept the lead during at least half a century. Other pioneer growers were S. and J. Rinz, in Frankfurt; Johann Zennick in the same place, who were later on followed by the brothers Mardner at Mainz, and C. H. Müschen at Cantor, near Teterow.

France had several florists and amateurs who successfully raised new Dahlias; these men were also known as producers of new varieties of other garden plants—Chéreau, Guénot, Leroy, Lorain, Miellez, Milcent, Soutif, Voisenon, and others.

In Belgium such world-famous firms as Charles van Geert, in Antwerp, and Louis van Houtte, in Ghent, were extensively Dahlia growers in the earliest period of its development, and in the 'forties they offered several Dahlias of Belgian origin, partly of their own raising.

In Holland, Affourtit's grandson, who was established at Utrecht as a florist, obtained very good varieties between 1850 and 1860, which quickly found their way abroad. His best-known varieties were the Fancy Dahlias Sieraad van Kweeklust, a pure rosy-red; Mevrouw Hacke van Mynden; the excellent whites Mevrouw Krelage, Cornelia Suzanna Affourtit, and Mejuffrouw Toussaint; the curious Laurens Koster, almost black, edged fiery-red, with white tips; Mr. Bilderdijk, sulphur yellow, with lilac edging; another Fancy Dahlia, Chinesche Vrouw; C. De Winter, a giant rose-lilac flower; and Dr. J. H. Molkenboer, with large violet purple flowers. Several other firms yearly issued special Dahlia catalogues which contained extensive lists of the introductions from all surrounding countries.

The quality of the flowers, from a grower's standpoint, steadily improved. The first decided advance was made in 1832 by the raising of Springfield Rival, described as a superb crimson flower. In 1840—special Dahlia shows were already held yearly in many places—popular flowers, such as Sharp's Beauty of the Plain was exhibited in 89 stands, 44 of which were first prize stands. Cox's Defiance, a yellow Dahlia, was shown in 41 first prize stands. Two of the best flowers in 1841 were Conqueror of the World, yellow, slightly tipped, and Rival Revenge, a yellow flower, very much ribbed and decidedly inferior as a show flower, as compared with those we knew thirty years ago. The same remark applies to the celebrated Burnham Hero (1841), Whale's Attila and Beauty of Wakefield (1842). Shortly afterwards the flowers had so much improved that only one variety exhibited in a first prize stand in 1846 was exhibited six years previously, and that variety was Springfield Rival.

The public is always seeking for something extraordinary, and in the case of the Dahlia it was not satisfied with the endless variety of colours; in 1846 it wanted a blue variety. The Caledonian Horticultural Society of Edinburgh promptly offered a prize of £1,000 to the raiser of such a flower, and the Irish sister society doubled the prize to £2,000. We cannot find any trace of a result, and, although Robert Cannell was introduced forty-five years later as a "blue Cactus Dahlia," which really had a magenta shade, the public is still expecting the true blue flower.

The idea of the Scottish and Irish societies did not satisfy the editor of the French *Revue Horticole*, who wrote:—"*Nous avons toujours été du nombre des plus zélés promoteurs du progrès de l'horticulture, mais nous renonçons à exprimer ici les sentiments qu'ont fait naître en nous la lecture de ce programme. Proposer cinquante mille francs pour un Dahlia, en Irlande, dans ce malheureux pays, où la famine est devenue une maladie endémique, c'est insulter à la misère publique.*"

The German growers came to the front with England's Rival (1840?), Triumph von Köstritz (1849), Deutsche Sonne (1859), and a host of others.

(To be continued.)

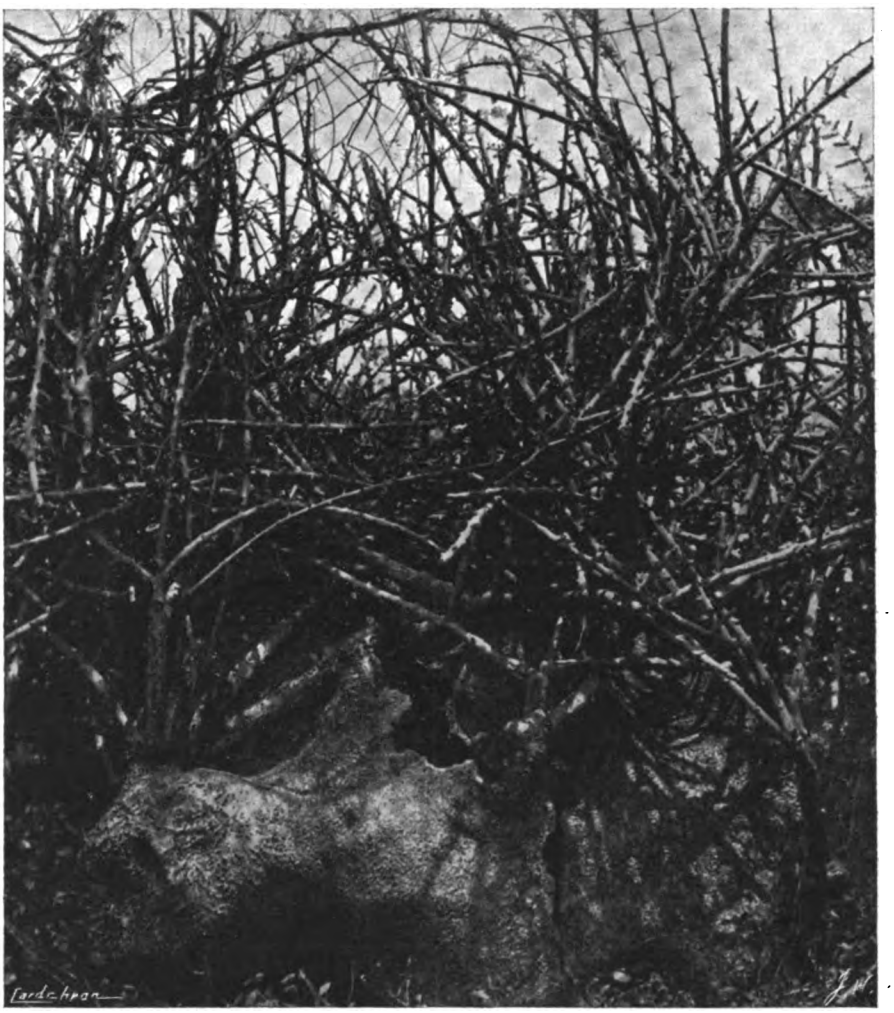

FIG. 82.—A "GIANT AERIAL BULB," PROBABLY ADENIA GLOBOSA, IN EAST AFRICA (SEE P. 219.)

* A paper read by Mr. Ernst H. Krelage before the International Horticultural Congress at Amsterdam, on September 19.

THE BULB GARDEN.

TULIPA BATALINI.

Tulipa Batalini, which I had perforce to leave behind in the garden I formerly owned, remains a very pleasant memory. It is a scarce Tulip, and not so cheap as one would desire. It appears to need a light, dry soil, with a good deal of sand in it, and should be planted about three inches deep. It has a dwarf habit; its leaves grow almost prostrate on the ground, and the stems grow only about six inches high—sometimes four only and sometimes eight—and bear good flowers of light yellow, almost creamy-yellow, in fact, touched with a line of red at the tips of the segments. It is best adapted for a sunny rockery, where it can be well rested during the summer.

ORNITHOGALUM NUTANS.

For a bulbous plant with spikes of silvery appearance when in bloom I can confidently recommend the old Nodding Star of Bethlehem, Ornithogalum nutans, a plant far too little grown, and a lovely thing when grown in grass or in clumps in the border or rock garden. It looks best when it has a carpet of greenery through which to bloom, as its leaves wither before the flower is in full perfection, and, if on bare ground, the plant is thus shorn of some of its attractions. It grows to various heights, according to the soil, and is often a foot or two in stature, giving a pleasing inflorescence.

The flowers open gradually at the bottom of the spikes; pretty, drooping, starry bells, with a ground colour of white, veined on the outside with a broad veining of green, which gives the blooms a remarkably silvery appearance.

I was much pleased to observe an appreciative remark regarding this Star of Bethlehem from a distinguished amateur cultivator of hardy flowers, whose taste is of the highest, and who appreciates this Ornithogalum very greatly. It is not an expensive bulb by any means, and may be bought in quantity at a cheap rate. Where planted in clumps three to five bulbs will make a good start; but in grass the bulbs should be planted in an irregular fashion. An excellent way is to take a handful, throw them down and plant them where they fall. Self-sown seedlings will come up, and add to the beauty of the mass planted in the grass.

O. nutans is perfectly hardy, and may be planted when bulbs arrive in autumn at a depth of from 2 to 4 or 5 inches, shallower in strong soil than in that which is light.

THE AUTUMN SNOWFLAKE.

Readers who wish to cultivate the exquisite little Autumn Snowflake, Leucojum autumnale, should endeavour to secure the bulbs as early as possible in August, and plant them as soon after they are received as convenient. If planting is done in good time it is likely that flowers will be produced, so that the grower may have a foretaste of the pleasures he will derive from this Snowflake when it has become established, and the bulbs have increased so as to present a little clump. The foretaste will be a charming one in itself, as we see the little, slender, chocolate-coloured stems and the delightful little drooping bells, satin-like in their lustre, and of a charming white just touched with a flush of warmer colouring. Before the flowers pass away the narrow grassy leaves are produced and last during the winter. For a warm spot in the rock garden Leucojum autumnale is a veritable gem. It grows best in sandy soil mixed with leaf-mould or peat and it needs perfect drainage. I believe it to be quite hardy; but I have seen it covered with a bell-glass or hand-light in the north—a precaution I have never found necessary. Planting should be done so that the crowns are an inch underneath the surface. The advice to plant as early as possible is justified by the fact that this Autumn Snowflake generally flowers in August and September if grown in a warm position, and in some seasons I have had it in bloom by the end of July. At any time, however, this charming flower is welcome, and no one will regret its addition to the treasures of the garden if suitably planted and well established. *S. Arnott.*

PUBLIC PARKS AND GARDENS.

The civic authorities of Aberdeen, headed by Lord Provost Meff and Councillor Roberts, convener of the Links and Parks Committee, made a tour of inspection of the city parks on the 18th ult. Accompanied by Mr. W. B. Clark, the Superintendent of Parks, the Town Council visited all the parks, bowling greens, tennis courts and golf courses belonging to the city, and all were greatly impressed with the excellent condition of the parks and the manner in which things are done by Mr. Clark. Subsequent to the inspection, when tea was served at the Duthie Park, Lord Provost Meff gave the toast of the Links and Parks Committee, and expressed his high appreciation of the great asset their fine parks were to the city. They had to-day, he said, in Councillor Roberts a convener who devoted a tremendous amount of time to his department, and who was in the proud position that day of showing them a number of parks and public places that could not be surpassed by those of cities much larger than Aberdeen. In Mr. Clark, their superintendent, they had a very capable official, who had remained with them even when he was assured of securing the plum of his profession (superintendency of Edinburgh Parks). Councillor Roberts, in reply, said it was a great pleasure to him to have the city fathers there that day. They had certainly seen much, but they had not seen all Mr. Clark, their superintendent, had to look after, for besides the parks he had charge of the trees throughout the city, numbering nearly 6,000, and the children's playgrounds. He associated himself with what had been said concerning Mr. Clark's ability and the intense interest he took in his duties.

In reply to the toast of his health, which was proposed by Baillie Wright in very warm terms, Mr. Clark, the superintendent, thanked the council for the courtesy and kindness they had extended to him in his duties, and went on to say that while in Aberdeen they had a considerable area of parks, they had not a piece of ground on which to grow plants to replenish the parks. They had to go to local nurseries and take what was to be got there. With regard to trees for the city streets, the local nurserymen did not grow trees for that purpose, but for cover, and the result was that some of the trees in the streets of Aberdeen were a disgrace through nothing better being obtainable. He advocated the provision of a field—preferably at Hazlehead Park—which could be utilised as a municipal nursery. Were such provided they could grow their own plants and trees as well as turf for returfing the bowling greens.

Bethlem Hospital, Southwark, the site of which was formerly St. George's Fields, is likely to be removed, and it is suggested that the present building should become a museum and picture gallery for South London, and the grounds a public park.

MARKET FRUIT GARDEN.

After an unsettled August it was hoped that September would be fine, but that hope was not realised. It is true that the month opened and closed well, but there was a period of twelve days, from the 14th to the 25th inclusive, when rain fell every day, often accompanied by gales which brought down much fruit, including late Plums. The weather became thoroughly autumnal, and fruit trees responded by the yellowing of the leaves, though the ripening of the fruit was still delayed. The gathering of the crops was hindered, and the demand for fruit fell off, as it always does when the weather is cool and dull. A start was made with much-needed hoeing and cultivation early in the month, but this had to be abandoned when the rain came, and the labour transferred to the mowing of litter in the grass orchards. Weeds grew fast on the arable land, and it is to be hoped that October will give an opportunity of cleaning this, as much spring work is saved if the plantations can be got into good order before winter.

Plums Finished.

The Plum crop lingered until late in September. The total yield of my orchards was 972 half-sieves, as compared with 2,745 last year. Prices, although high for Plums, did not compensate for the short crop. The average net return per half-sieve was 11s., as against 6s. last year. Thus the price was less than double, whilst the crop was little more than one-third. Imports from the Continent, including large quantities of German Plums late in the season, prevented home growers from securing the full value of their light yield. Monarch was the only variety which with me, cropped better than last year, though Victoria fell very little short. Curiously enough, the mid-season varieties, such as Czar, Victoria and Belle de Louvain, which are often very cheap, brought the best returns, if we except the very few Presidents which formed the final consignment.

The generally unfavourable character of the year for fruit of all kinds extends even to nuts. I gathered only 383 lb. of Cobs from about four acres of trees, which yielded 4,395 lb. last year.

Late Apples.

The later varieties of Apples are maturing very slowly, but some of the cooking Apples are proving much more plentiful than the early varieties. Lane's Prince Albert is quite the crop of the season. This has been gathered, and, with Bramley's Seedling, will be stored away until prices improve. Although very heavy imports are expected, and home growers have been advised to market all their Apples as soon as possible, I doubt if this is wise in the case of cooking varieties. The imported Apples are used chiefly for dessert, and do not compare with such kinds as Lane's Prince Albert and Bramley's Seedling for cooking. I shall be surprised if the market for these does not improve when the home supply nears exhaustion.

Apple Calville Rouge d'Automne.

A few years ago I noticed on a huckster's cart a box of brilliantly red Apples, which had been bought from a neighbouring farm orchard. They were so very striking in appearance that they appealed strongly to me as a good variety to grow for market. I went to the farm, and was shown the tree, a miserable specimen half smothered by others in the usual kind of neglected farm orchard; but I was told that it cropped well and regularly. New shoots were scarce, but I secured a few for use as scions, and have raised several trees. These carried half a dozen fruits this year. The variety has been named for me as Calville Rouge d'Automne, often called Sops-in-Wine. Mr. E. A. Bunyard tells me that he has a tree of this Apple in his orchard, but that it always comes rather too uneven to make a good market variety. I think, however, that it may be specially suited to my light soil and early district; and I shall work up a stock and try to popularise the fruit in local markets. It seems to be the kind of Apple that is wanted to follow Worcester Pearmain. The colour is quite as brilliant, staining through even into the flesh in a sunny season, and the flavour is better, which does not say too much for it. Hogg describes it as a culinary Apple of inferior quality in this country, but highly esteemed on the Continent for both culinary and dessert purposes. He states that the tree is a strong and vigorous grower, and an abundant bearer; and that it should be grown as an open dwarf on Paradise stock in a fine sandy loam, and not too closely pruned. Its season here appears to be late September and October.

Grass Orchards Popular.

More and more growers are favouring the practice of grassing down established Apple orchards. They find that, though they sacrifice a little in size of fruit, they gain more than enough to compensate for this in colour and skin quality. Some of them claim also

Digitized by Google

that they get less trouble from pests and diseases. In most cases the grass is kept down by grazing with pigs or sheep, or by running poultry under the trees. I believe that this is a move in the right direction, if only because it reduces the cost of cultivation. Orchard fruit can hardly pay for hand hoeing at the present cost of labour. I find that several varieties do better on grass, including Allington Pippin, Worcester Pearmain, Beauty of Bath, and Blenheim Pippin. But on my land, which lacks organic matter and is apt to suffer from drought, I prefer to mow the grass and leave it on the surface as a mulch, rather than feed it off. I believe that the "sod strip" system, in which the actual tree rows are on strips of turf mown twice a year, with the alleys between the rows kept cultivated by horse-drawn implements only, is going to prove ideal for my conditions of soil and climate.

It cannot be too strongly emphasised, however, that grassing down must not be done until the trees are thoroughly established, say at least ten or twelve years from planting. Up to that time they must be in cultivated ground, or, at any rate, must have a cultivated space extending slightly beyond the spread of the branches round each tree. It ought not to be necessary nowadays to urge this; but examples of young trees simply stuck into grass land are still frequently seen; and it is always clearly apparent that such trees are doomed to permanent stunting and failure.

DRESSING WOUNDS ON FRUIT TREES

A satisfactory dressing for wounds on fruit trees has yet to be found. It is badly wanted, because many of the worst fungous diseases, including Silver-leaf, enter the trees through wounds made in pruning, or where branches are broken. I have generally painted all large wounds with Stockholm tar, but, according to trials made at the Long Ashton research station, this is of little use, as it does not stand the weather well. These trials have not gone on long enough to test the various dressings with regard to disease prevention, but some observations have been made as to the nature and rate of callus formation, the weathering of the dressing, and the ease of application. Only a few of the applications tried weathered at all well. Clay and cow dung, Stockholm tar, gas tar, a grafting compound, boiled linseed oil and chalk, all weathered more or less badly. Anti-fouling paint (used on ships' bottoms) weathered extremely well, but is apt to cause killing of the bark, a fault shared by lysol, gas tar, and gum arabic. Callus formation is favoured most by dressings which are not antiseptic, but which aim chiefly at keeping the wound moist. These include surgical tape, grafting wax, and a mixture of clay and cow dung. White lead paint weathered well, and appears to have been free from objection.

According to Messrs. F. T. Brooks and H. H. Storey, who are investigating Silver-leaf disease at Cambridge and at the John Innes Institute, gas tar has given the best results so far. They consider that there is no danger of this substance injuring the bark if it is applied carefully to the wound so as not to extend on to the healthy bark. In their experiments Stockholm tar gave very disappointing results, but white lead paint produced fair protection. Anti-fouling paint gave excellent protection, but in some cases killed considerable areas of bark around the wounds; but it is hoped to make some improvement in this dressing. The need for renewing the dressing, say after three months, is urged by these experimenters, because the swelling of the callus causes the best of dressings to crack. The prompt application of the dressing after making the wound is also recommended, as fungi enter most easily whilst the wound is fresh.

It will be seen that the most hopeful dressings at present are gas tar and white paint. I know from experience that gas tar applied with reasonable care does no harm to the bark; and I shall substitute this in future for Stockholm tar.

There is one dressing used by some growers which does not seem to have been tested in these trials. That is a solution of copper sulphate. This soaks right into the wood, of course, and does not form a weather-proof covering to the wound; but it is such a strong fungicide that it may protect it from infection for some time. Anyhow, some growers believe that it heals up canker wounds quickly. I have also heard of undiluted Bordeaux paste being used with satisfaction.

IMPERIAL FRUIT SHOW.

The growers' classes at the Imperial Fruit Show, which will be held at Manchester from October 26 to November 3 inclusive, should be more attractive and instructive than they have been on previous occasions, because the packing will not be upset by the judges in making their awards. Hitherto it has been necessary for them to dive into the boxes to examine the fruit in the lower layers, and consequently, visitors have come away with the impression that English growers do not understand how to pack Apples in boxes. This year each entry consists of seven boxes instead of six; and the judge will select any one of these to turn right out and examine thoroughly. The fruit in this box will not be shown at all, but the remaining six boxes will be exhibited undisturbed.

The holding of the show in Manchester is pleasing to the Eastern Counties and West Midland growers, for whom the northern markets are very much more important than London. *Market Grower.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante, pp. 71-76.)

(*Concluded from page* 206.)

WALES.

GLAMORGANSHIRE.—Fruit in these gardens is scarce generally, especially Pears and stone fruits. We have a fair crop of Apples, the best varieties being Codlins, including Lord Grosvenor and Lord Suffield on trees on a covered walk, Worcester Pearmain, Allington Pippin (the heaviest crop of all), Warner's King, Frogmore Prolific, Lane's Prince Albert, Bramley's Seedling, Tom Putt and Norfolk Beauty. Of Pears we have a few fruits of Beurré Hardy, Conference and Doyenné du Comice, but no early or very late ones. We had a few Victoria and Early Prolific Plums on wall trees, but no Damsons or Cherries. There were heavy crops of Royal Sovereign and King George Strawberries, and an average crop of Raspberries, including Lloyd George, Park Lane and Superlative. Black Currants, Victoria and Seabrook's Black were plentiful, but not of the best quality. Red Currants and Gooseberries were both plentiful. Our soil is all that could be desired for fruit cultivation. *W. E. Wright, Henstaff Court Gardens, Pontyclun.*

IRELAND.

KILKENNY.—I have never known a worse year here for tree and wall fruits. An exceptionally mild winter was followed by a cold spring, with continuous east winds, and morning frosts, from early April until June. There was plenty of fruit blossom of all kinds, but the conditions were unfavourable, and very poor crops have resulted. Added to this there was no rain from mid-April until July. This drought reacted very unfavourably on most promising bush and small fruit crops. As was to be expected, the unfavourable weather of spring and early summer favoured aphis attacks; aphides and the capsid bug on some young Apples trees have proved our worst pests this season, little or no damage having been caused by caterpillars. The soil is a medium and very fertile loam, overlying subsoils varying from sand to yellow clay. *T. E. Tomalin, Bessborough Gardens, Piltown.*

——The cold weather during spring retarded the blossoming of fruit trees until May, and the weather was not very good at the time when the fruits were setting. The great quantity of Pear blossoms was very exhausting to the trees, and comparatively few fruits set. Apples and Plums were failures. Small, soft fruits were rather below the average, excepting Strawberries, which gave a heavy crop of good flavoured berries, and Raspberries, which were plentiful. Our best varieties of Strawberries are Royal Sovereign, King George, Givon's Late Prolific and Laxton's Latest. Peaches and Nectarines out-of-doors were very disappointing, which is accounted for by the fact that a sharp North-Easterly wind prevailed at the time of the trees flowering. *J. W. Grahame, Flood Hall Gardens, Thomastown.*

MEATH.—This district is one of Ireland's best fruit districts, and this year there is not a peck of fruit to each ton gathered last year. I never saw such a total failure of the crops. The weather of spring after February was of the severest kind, and the blossom perished in the wintry conditions. *Michael M'Keown, Juliana town, Drogheda.*

TYRONE.—We have the worst crops of Apples, Pears and Plums for over 30 years. Cherries are grown only in very limited number, but they were a little better, although not a good crop. This is due, I consider, partly to the excessive crops of last season, which weakened the trees, and partly to the inclement weather experienced in April and May. Bush fruits were fair crops, but Raspberries were rather scarce. Strawberries were a fair crop, but were fully a fortnight late in ripening. The soil is a very heavy binding clay. *Fred. W. Walker, Sion House Gardens, Sion Mills.*

CAVAN.—This is one of the worst years in County Cavan on record for Apples, Pears and stone fruits. The blossom was late in opening and all the fruits failed to set. During the period of flowering the wind was from the north, and frost and hail were frequent. Gooseberry mildew is prevalent in this district. Small fruits were extra fine crops. Strawberries were good, but about ten days late in ripening. *Edward Rutherford, Farnham Gardens.*

DOWN.—With the exception of Apples, we have average crops of most kinds of fruits. Gooseberries were more than usually abundant, and although we had a long spell of cold, cutting winds at blossoming time, I think exhaustion from over-cropping last year is the chief cause of the failure of the Apple crop. *T. W Bolas, Mount Stewart Gardens, Newtownards.*

CORK.—On the whole this is a very disappointing fruit season. Many varieties of Apples have good crops, but the fruit is undersized. Pears are a complete failure. Plums set well; but, as a result of the persistent cold north and north-east winds and prolonged drought during May and June most of the fruits dropped. Of bush fruits Gooseberries were the best, the crop being above the average. The rainfall for May and June combined only amounted to 1.10 inch, and the effect of the long drought and harsh winds was apparent on all crops, particularly Strawberries, Black Currants, and Raspberries. Aphis has been very troublesome, and caused much damage where spraying was neglected. *J. Dearnaby, 17, St. Patrick's Terrace, Magazine Road, Cork.*

WATERFORD.—Fruit generally is scarce; late spring frosts, harsh winds, and hail showers did much harm to the fruit blossom. In the case of Pears the unfavourable weather, when Pear trees and some varieties of Apples were in full flower, practically ruined these crops. Small fruits were very good; Black Currants and Gooseberries being heavy crops. Peaches and Nectarines in the open were badly attacked with leaf blister and mildew. I have treated these pests, but the fruit was inferior. Apricots are not a success here. Cherries dropped considerably, and the few that ripened were of poor quality. The soil is of a heavy, clayey nature. *William H. Arrowsmith, Curraghmore Gardens, Portlaw.*

CHANNEL ISLANDS.

JERSEY.—The fruit crops are not very favourable; everything seemed to suffer badly from the cold, wet weather in the spring. In some instances there is an average crop, but the fruits dropped freely in summer. *Thomas Sharrenan, The Imperial Nursery, St. Mark's Road, St. Heliers.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Scum on Ponds.—If *A. H.* (see p. 166) wishes to get rid of the green Algae which are causing the scum on his lake, I would suggest that the best material to use would be copper sulphate of 98-99 per cent. purity in the form of small crystals. The amount required should be placed in a coarse bag, and then be pulled very gently backwards and forwards through the water as close to the surface as possible. It would be best to select as warm a day as possible, as it has been found that temperature has a very great influence on the effect of copper. It is, of course, always better to use copper sulphate as a preventive rather than as a cure, and the cost of treatment is naturally much less. The quantity to be used depends on the size and depth of the pond; but to calculate the cubic contents multiply together the length, breadth, and average depth in feet, and then, in order to obtain the number of gallons of water to be treated, multiply the result by 6. For every 10,000 gallons of water to be treated 2½ ounces of pure copper sulphate 98-99 per cent. purity would be required, and if applied in this proportion no injury should be caused to either fish, or plants such as Water Lilies. In America copper sulphate has been used extensively during recent years, not only for preventing the growth of Algae in reservoirs, but even for the clearing and cleansing of reservoirs and ponds covered with offensive smelling scum. The use of copper sulphate for the purpose of removing the objectionable odours caused by the decay of water plants is of great importance, and there is little doubt but that the treatment of water in this manner will probably be found to have the most favourable effect in keeping mosquitoes from using water so treated as their breeding places. *Robert W. Ascroft.*

Hardiness of Cobaea scandens.—With reference to the note in *The Gardeners' Chronicle* of September 22 respecting the hardiness of Cobaea scandens by Mr. C. Orchard, The Cottage, Smoglands, Bembridge, I.W., I would observe that I sowed seeds in February, 1922, for the purpose of raising plants for planting against 9 ft. columns and to cover chains (that hang from one column to another) until the permanent climbers were established. The seedlings were potted into 4½ inch pots and planted at the base of the stone columns early in June. They grew up, covered the chains, and flowered from the end of August until late autumn; during the winter of 1922-3 they had no protection whatever. This year they grew away strongly and have flowered continuously, which surprised me not a little. The Cobaeas are growing in heavy loam incorporated with leaf-soil and old mortar rubble. *F. Clipstone, Melchet Court Gardens, Romsey, Hampshire.*

——I give another instance of the hardiness of Cobaea scandens. In July, 1922, a seedling of C. scandens was planted against a wall facing south-west, near a bay window at the District Hospital here. It flourished well and bore a good many flowers during the autumn, and a few during the winter. In April a ripe capsule was gathered, seeds from which I sowed at once in a gentle hot-bed. These germinated, the seedlings were through the soil in less than a fortnight, and have grown into strong plants. The old plant now covers a space of several square yards, and has hundreds of buds, flowers, and fruits. This summer a small plant of Tricuspidaria lanceolata in my garden formed one fruit, which ripened in September, and contained four good seeds. I do not know whether this is an uncommon occurrence or not *W. A. Shoolbred, F.L.S., St. Ann's, Chepstow.*

Phygelius capensis.—I was interested in the recent short article devoted to this plant (see September 29, p. 183), and can endorse what *A. T. S.* writes about its hardihood. I have in mind a clump of Phygelius which has been growing merrily in a Cumberland garden (eight miles inland from the Solway Firth) for thirty to forty years. It has always occupied the same position in a sheltered border facing south, and flowers regularly. At times it has had to withstand fairly severe frosts, for we are not so frost-free in this part of England as is sometimes imagined. *J. P., Carlisle.*

Notes on Some of the Newer Daffodils.—A friendly critic points out that in my article on "Some of the Newer Daffodils" which appeared in *The Gardeners' Chronicle* of September 22 (p. 173) there were two or three slips:—(1) Magnolia (IV., b.) was not raised by Mr. Engleheart, but by the Brodie of Brodie. (2) Venetia did obtain an Award of Merit, a point I was not sure about; it was raised by Mr. Hy. Backhouse. (3) Fortune I unfortunately described as having a light yellow perianth, whereas it is bright golden yellow. Had I grown the flowers, the mistake would never have been made; perhaps I was so dazzled by the orange cup that the perianth was forgotten! Having planted four nice bulbs, I hope to become better acquainted with the flower next spring. *J. Duncan Pearson, Lowdham, Notts.*

St. Cuthbert's Cole (pp. 136, 177).—By an unfortunate omission, Mr. Brotherston's note does not give references to the sources whence he derives his information. I am not calling the accuracy of this in question, but the matter is so interesting that one would like to be able to trace it to its source. There are evidently mis-spellings in Mr. Brotherston's transcript—*e.g.*, "Hieracium Spondylium" for *Heracleum Sphondylium*—and the extracts may contain others, which a reference to the sources would enable one to correct. *James Britten.*

Second Crop Pears.—On October 2 I saw a most remarkable second crop of fruits on a William's Bon Chrêtien Pear, many of the fruits weighing 8 ounces to 10 ounces. It was interesting to notice that every fruit was carried singly on the extreme end of a precocious spur, which seemed to have grown quite distinct and separate from the basal cluster. I examined a Beurré Bosc which has fruited in the same way, and thought the matter worthy of attention, as these fruiting spurs appear to be of biennial maturity, and after close inspection I conclude they will not interfere in any way with next season's set. *Pomona.*

Cercidiphyllum japonicum.—This tree is certainly very beautiful at this season; but the note concerning it, signed *T.* (page 183), in describing it as a "deciduous shrub," will be apt to mislead planters. It is one of the taller Japanese trees, and Mr. J. H. Veitch has recorded a specimen at Hakodate, with a stem girth of 21 feet (*A Traveller's Notes*, page 131). *Herbert Maxwell, Monreith.*

Poa annua as a Perennial? (see p. 149).—Mr. Baker makes interesting reference to this grass. That it is a good grass for town lawns, particularly in smoky areas, is, we believe, well established. We think it was the late Mr. Nicholson, of Kew, who, writing in *Gardeners' Chronicle* a number of years ago, pointed out that the so much admired plots in the neighbourhood of Westminster Abbey are composed entirely of this species. That it is an annual is, we think, incontrovertible, but under favourable conditions it is thoroughly permanent by constant self-seeding. Like most annuals it fares badly in a close sward of perennials, so that if there is a good prospect of a general lawn mixture succeeding it would be a waste to include Poa annua, which, if used, should be sown by itself. Besides, the pure seed is scarce and expensive. In districts like Lancashire, where chemical factories often pollute the air to the detriment of vegetation, this grass would come out on top, the class of competition being entirely in its favour. It is often a troublesome weed on market gardening or nursery lands. Here it is our greatest pest, flowering and seeding the whole year round, and stooling as freely as Chickweed. P. trivialis is another troublesome weed here in parts, though not to be compared with P. annua. *William Power and Co., Waterford.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

A meeting of the Floral Committee was held at the Royal Horticultural Hall on Monday, September 17, when no fewer than thirty varieties came up for judgment. Awards were made as follow:—

First Class Certificates.

Shirley Sunset (II, 1, c).—A very attractive border variety of golden-bronze colour. Shown by Mr. H. Woolman, Shirley, Birmingham.

Lichfield Bronze (II, 1, c).—A rich deep bronze coloured border variety, with flowers of excellent substance. Shown by Mr. Thorpe, Lichfield.

Commendation.

Royal Salute (II, 1, c).—A very effective decorative variety for the border, with bright chestnut-red flowers. Shown by Mr. H. Woolman.

September Yellow (II, 1, b).—A soft yellow-coloured variety with large, elegant flowers, something after the character of George Wormig. It is a sport from the popular September White. Shown by Mr. Thorpe.

The Floral Committee met again on Monday, October 1, in the Bandstand at Holland Park Hall, when a goodly number of attractive varieties were brought forward, and the following awards made:—

First Class Certificates.

Royal Salute (II, 1, c).—A variety Commended at the previous meeting and now shown in particularly fine form. Its chestnut-red flowers attracted a great deal of attention. Shown by Mr. H. Woolman.

Minstrel (II, 1, c).—A large Japanese-flowered border variety, with crimson flowers of considerable substance. Shown by Mr. H. Woolman.

Shirley Terracotta (V, 1, a).—A deep terra-cotta coloured single variety of large size. Apparently it is very free flowering. Shown by Mr. H. Woolman.

Doreen Woolman (V, 1, a).—An exceptionally attractive single variety for garden decoration, bearing its bright terra-cotta—almost a rich apricot shade—single flowers in sprays, on long, stiff stems, therefore constituting a variety extremely useful for cutting. (See Fig. 78, p. 211.) Shown by Mr. H. Woolman.

Mrs. Jack Pearson (II, 1, c).—A very useful orange-bronze coloured variety, which is continuous flowering from the middle of July until severe frost sets in. This variety was described and illustrated in *Gard. Chron.*, February 3, p. 65. Shown by Mr. P. Ladds, Swanley, Kent.

September Yellow (II, 1, b).—This is the soft yellow sport from September White, which received a Commendation at the previous meeting. Shown by Mr. D. Ingamells.

Commendation.

Purple Flag (II, 1, b).—This has medium-sized flowers of a rich purple-amaranth colour, with dull silver reverse, and it will appeal especially to those who care for this particular shade. Shown by Mr. H. Woolman.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

September 6.—Committee present: A. Hanmer, Esq. (in the chair), Messrs. J. Birchenall, A. Burns, A. Keeling, E. W. Thompson and H. Arthur (Secretary).

First Class Certificates.

Laelio-Cattleya Mrs. Medo (*C. Venus* × *L.-C. Luminosa*), a well-shaped flower of brilliant colour. From S. Gratrix, Esq.

Odontoglossum Helma (*parentage unknown*), a heavily marked variety.

September 20.—Committee present: R. Ashworth, Esq. (in the chair), Messrs. J. Birchenall, A. Burns, D. A. Cowan, A. Coningsby, J.

Digitized by Google

Cypher, J. Howes, A. Keeling, E. W. Thompson and H. Arthur (Secretary).

First Class Certificates.

Laelio-Cattleya Momus var. Mirimar (*rubens* × *Octave Doin*), a large flower with very broad sepals and petals of deep rosy-mauve colour, and a rich amethyst-purple lip, with golden lines in the throat. From Mrs. Gratrix.

Brasso-Laelio-Cattleya Thompsonii alba (*B.-L. Dighyano-purpurata* × *Gaskelliana alba*), a pure white variety, the large lip having a rich orange throat. From S. Gratrix, Esq.

Brasso-Cattleya Sofrano var. Primrose Queen (*C. iridescens* × *B.-C. Mrs. Leemann*). The large lip of this well-shaped flower is beautifully frilled and coloured Primrose-yellow throughout. From Messrs. Cowan and Co.

Awards of Merit.

Cattleya Thebes (*aurea* × *Adula*) and *Cattleya amabilis alba*. From P. Smith, Esq.

Sophro-Laelio-Cattleya Thyone (*S.-L.-C. Marathon* × *C. Thyone*) and *Cypripedium Godefroyae ochroleuca*. From S. Gratrix, Esq.

Groups.

S. Gratrix, Esq., West Point (gr. Mr. J. Howes), was awarded a Gold Medal for a group in variety.

Messrs. J. Cypher and Sons staged a group for which a Silver Medal was awarded.

HOLLAND PARK HALL SHOW.

(*Concluded from p.* 212.)

Single Dish Fruit Classes.

By far the largest number of classes in the competitive fruit section is devoted to single dishes of Apples and Pears, and usually a very large number of exhibits are staged, but this year, in keeping with the rest of the fruit show, the number of entries was down considerably and the majority of the prizes were divided between three competitors, namely, J. A. Stidson, Esq., Captain Drummond and the Earl of Bessborough. Although the numbers of exhibits staged were fewer it is satisfactory to know that there were entries in nearly every class. The largest number of entries was for Apple Cox's Orange Pippin, in which six competed. The first prize was won by J. A. Stidson, Esq., with very choice fruits, and this grower also won first prizes for American Mother (three entries), Ellison's Orange (two entries), St. Everard (two entries), King's Acre Pippin (two entries), St. Edmund's Pippin (of which he was the only exhibitor), and for eight fruits of any early variety not named in the schedule, with Autumn Pearmain.

The first prize for a late variety not specified in the schedule was won by the Earl of Bessborough, with King of Tomkin's County, who also excelled in the classes for Blenheim Pippin (five entries), Charles Ross (one entry), and Adams's Pearmain (two entries).

Capt. Drummond was successful in the classes for Allington Pippin (three entries), James Grieve (four entries), Lord Hindlip (two entries), Ribston Pippin (five entries), and Sturmer Pippin (of which he was the only exhibitor). Of the remaining prize winners, R. Basil Hoare, Esq., was first out of five exhibitors for Rival.

In the corresponding division for cooking Apples the largest number of first prizes was won by the Earl of Bessborough.

He excelled for Bismarck (two entries), Dumelow's Seedling (one entry), Ecklinville (three entries), Norfolk Beauty (two entries), Grenadier (one entry), Golden Spire (one entry), and Lane's Prince Albert (six entries). The first prize was also won by the Earl of Bessborough for fruits of Loddington, in the class for eight fruits of any variety not named in the single dish classes.

Viscount Hambledon was successful in the classes for Beauty of Kent (one entry), Edward VII. (one entry), and Blenheim Pippin, large fruits (four entries), whilst Captain Drummond excelled in the classes for Lord Derby (four entries), Newton Wonder (two entries), Stirling Castle (one), and Warner's King (six entries).

The best fruits of Bramley's Seedling were those shown by J. A. Stidson, Esq., who was first out of five competitors, and who was also placed first of two in the class for Peasgood's Nonesuch, and first of three in the class for The Queen. R. Basil Hoare, Esq., was the sole entrant in the class for Emneth Early (Victoria), as was Sir C. Nall-Cain in the class for the Rev. W. Wilkes, and both received the first prize. Major G. Baynes was first in the class for Annie Elizabeth, for which two entries were forthcoming.

In the division for Pears, entries were even fewer than in that for Apples. In the dessert section Captain Drummond was the sole exhibitor in the classes for Durondeau, Easter Beurré, Emile d'Heyst, Marie Louise, Thompson's, Marguerite Marillat, and was awarded the first prizes, except in the case of Emile d'Heyst and Thompson's, where second prizes were awarded. The same exhibitor was also first out of three exhibitors in the class for Doyenné du Comice, and first in the class for eight fruits of any early variety not mentioned in the single dish classes, with Beurré d'Amanlis.

Sir C. Nall-Cain was first in the class for Conference (two entries), and for Louise Bonne of Jersey (three entries), whilst Mrs. Austin was first in the class for Glou Morceau.

There was no entry in the class for the best flavoured Pear not mentioned in the single dish classes, but in the corresponding class for Apples J. A. Stidson, Esq., was awarded the first prize for fine specimens of the variety Gravenstein.

ROYAL SCOTTISH ARBORICULTURAL.

On September 22 a number of the members of this Society paid a visit to Whittingehame, the East Lothian seat of Earl Balfour. They travelled by char-a-banc from Edinburgh, and on arrival at Whittingehame were conducted over the plantations and policies, where many fine Conifers and broad-leaved trees were seen, by Mr. W. Fife, the head forester. Among these was the famous Whittingehame Yew, under the canopy of which tradition asserts the plot to murder Darnley was hatched by Bothwell and his confederates, which, however, is extremely unlikely, as the calculated age of the tree will not permit of its having even been planted at that time. The bole is about 10 feet high and about 11 feet in girth, and the branches, which form a splendid head, cover an area of 100 feet in diameter. The tree is in excellent health, and the tops of the branches, which arch over and rest on the ground, over which they sweep, make good annual growths. Another interesting tree in the policies is the well-known Eucalyptus whittinghamensis, one of the many forms of E. Gunnii, and the parent of the plant at Kew, which was planted in 1896. The tree, which was raised from seed brought from Tasmania by the late Marquis of Salisbury when a young man, is in excellent health and regularly produces seed, much of which is fertile. A visit was also paid to the gardens under the leadership of Mr. G. F. Anderson, the gardener, who was complimented on their excellent condition.

From a sylvicultural point of view, the most interesting feature was the growing of Thuya gigantea in mixture with Larch and Beech. The Larches, as was no doubt anticipated, have taken a very decided lead, and are now beginning to threaten the existence of the Thuya. Consequently, as was explained by Mr. Fyfe, they are being gradually removed in order to give the Thuya more light and air. Larch makes excellent growth at Whittingehame, and the poles seemed remarkably free from canker.

The visitors were entertained to tea in Whittingehame House by Miss Balfour.

TRADE NOTES.

The Ministry of Agriculture announces that arrangements have been made by the Union of South Africa Authorities whereby Potatos grown in districts in this country in which Wart Disease has occurred only on isolated gardens and allotments will in future be admitted into the Dominion, provided that Wart Disease has not been known to occur on the land on which they were grown, that the actual Potatos are found on examination to be free from serious diseases and insect pests, and that a certificate to this effect accompanies each consignment.

All applications for the necessary certificates in respect of Potatos grown in England and Wales should be addressed to the Ministry at 10, Whitehall Place, London, S.W.1.

In accordance with the requirements of the Seeds Act, 1920, and the regulations made thereunder, it is necessary, in the case of a sale of any of the principal kinds of farm and garden seeds, for a statement to be made to the purchaser, at, or before, the time of sale or delivery, containing certain specified particulars as to the quality of the seed. These particulars must be based on a test carried out not earlier than August 1 preceding the date of the sales, except in the case of seeds sold during August and September, when the test may have been made since August 1 in the preceding year. In order to comply with the regulations, seedsmen and others carrying over stocks of seeds for sale from last season must, therefore, arrange to have them retested before offering them for sale as from October 1 onwards.

The Florists' Telegraph Delivery Association is holding its annual meeting at St. Louis, U.S.A., this week. The British unit has sent the following cable to the President:—"Fraternal greetings from the British unit of eighty florists all with you in spirit to sound the slogan, 'Say It with Flowers.'—Shearn (President), Brunton (Secretary)."

INQUIRY.

A correspondent is anxious to obtain information that will enable him to identify a hexagonal, bronzed badge. Obverse, garden basket and tools "Loyal and Independent Gardeners." Reverse, two men, each wearing cut-away coat, apron and sash, clasping hands, Rose and Vine left and right, "Let Brotherly Love Continue." Suspender, bunches of Grapes. Period, mid-nineteenth century.

GARDENING APPOINTMENTS.

Mr. L. W. Bush, for the past four years Foreman at The Mote Park, Maidstone, as Gardener to Lord Oranmore and Browne, Mereworth Castle, near Maidstone.

Mr. E. W. Hoyle, for the past two years General Foreman at Springfield Gardens, Marlow, Buckinghamshire, as Gardener to B. Eric Smith, Esq., Stubbings, Maidenhead, Berkshire.

Mr. Claude Fletcher, previously at Tottenham Trades Hall and Bermondsey Public Gardens, as Gardener to the Countess of Warwick, Easton Lodge, Dunmow, Essex.

Mr. G. Marcham, for the past three years Gardener to the Hon. Mrs. Skeffington Smyth, Stockton House, Codford, Wiltshire, as Gardener and Agent to J. E. A. Dubuc, Esq., Chicoutimi, Province of Quebec, Canada.

Mr. Edward Rutherford, for the past five years Gardener to Lord Farnham, Farnham, Cavan, as Steward-Gardener to J. Wilson, Esq., Hockley Lodge, Armagh. (Thanks for 2s. for R.G.O.F. Box.—Eds.).

Mr. E. R. Beames, for the past four years Gardener to Major Hague, Norman Hill, Dursley, Gloucester, as Gardener to W. H. Butler, Esq., The Priory, Westbury-on-Trym, Bristol.

Mr. Charles Jones, for two years and eight months Gardener-Bailiff to Cyril Gurney, Esq., Henlow Grange, Biggleswade, as Gardener to the Rt. Hon. Lord Manners, Avon Tyrrell, Christchurch, Hampshire. (Thanks for 2s. 6d. for R.G.O.F. Box.—Eds.)

ANSWERS TO CORRESPONDENTS.

BOOKS: *H. S.* The best work on hardy trees and shrubs for your purpose is *Trees and Shrubs Hardy in the British Isles*, by W. J. Bean. The best work on British wild flowers is Bentham and Hooker's *British Flora*, in two volumes, one text, the other illustrations. Both these works may be obtained from our publishing department, price £3 4s. 6d. and £1 4s. 9d., respectively, post free.

BEGONIA WITH RUSTY LEAVES: *J. K.* The rust on your Begonia leaves is caused by a mite, which may be destroyed by dipping the plants in an insecticide, or by dusting the undersides of the leaves with tobacco dust.

NAMES OF FRUITS: *E. N.* 1, Decayed, probably Lane's Prince Albert; 2, Norfolk Beauty.—*H. N.* 1, Summer Strawberry; 2, Mank's Codlin; 3, Cox's Pomona.—*E. S.* 1, Blenheim Pippin; 2, Hanwell Souring; 3, Adams's Pearmain; 4, Cox's Pomona; 5, Lady Henniker; 6, Cox's Orange Pippin; 7, Pear Marie Louise d'Uccle; 8, not recognised, deformed specimen; 9, Quarrenden.—*J. E. A.* Red Ingestre.—*J. N. A.* 1, Lord Derby; 2, Lane's Prince Albert; 3, Winter Hawthornden; 4, Ribston Pippin; 5, Newton Wonder; 6, Bramley's Seedling; 7, Lord Suffield; 8, King of the Pippins; 9, 10, and 12, not recognised; 11, Roi d'Angleterre; 13, Dumelow's Seedling (syn. Wellington).—*Kent.* 1, Golden Spire; 2, Mère de Ménage; 3, Scarlet Goldea Pippin.

NAMES OF PLANTS: *T. R. P.* It is impossible to identify your plant without seeing either a leaf or inflorescence. Probably it could be identified from an entire leaf. Judging from your description, we are inclined to think the plant is Curculigo recurvata variegata.

NEW SEEDLING DELPHINIUM: *G. F. E.* The Delphinium seedling has a spike and flowers of excellent size and quality, and the colour is such a charming shade of bluish-mauve that the variety seems to be well worth naming.

ORNAMENTAL OAK TUBS: *H. T.* You will be able to obtain these from horticultural sundriesmen, such as Messrs. W. Wood and Son, Beechwood Works, Taplow.

PYRUS AUCUPARIA CASTING ITS BARK: *J. H. S.* It is impossible to say from the specimens of bark received for examination what may have caused the fungous attack. A considerable quantity of mycelium was present in the bark and it is very doubtful whether the tree will recover. All that can be done is to remove the loose bark, paint the wood with a 20 per cent. carbolic solution, and when dry coat it with coal tar. The disease may have originated through an injury to the bark, through a broken branch or by root injury. Any dead branches that may be present should be cut out and the cut surfaces coated with coal tar.

TOMATO PLANTS DISEASED: *G. T.* It is impossible to state with certainty what disease is present in the dried-up specimen you send. Stripe disease is most readily controlled by liberal applications of sulphate of potash to the soil. If the disease has been exceedingly bad, sulphate of potash at the rate of half to one ton per acre should be applied in the base dressing, and nitrogenous fertilisers should be kept as low as possible. Should the plants develop stripe next year they should be dressed immediately with sulphate of potash at the rate of 5 cwt. to the acre. The white fly present in the houses should be destroyed when the crop is finished by fumigating with hydrocyanic acid gas at double strength. Should the fly appear next season it may be destroyed by fumigating with hydrocyanic acid gas or with tetrachlorethane.

REMARKS.—A moderate demand has prevailed during the past week. For some produce, notably Tomatos, trade has been very quiet, and large consignments received from abroad have kept values down, the low level of which has failed to attract buyers to any large extent. English Apples, although not plentiful, have been sufficient for the demand at ruling prices, and large shipments of Apples from Canada and the United States should bring about an easier tendency in this section. A few more English Pears have been marketed, but they are not plentiful. Choice fruits, such as Grapes, Peaches, Nectarines, and Melons are quoted easier. Grapes in particular are selling slowly. Plums from California, France and Central Europe are still available. Forced Mushrooms have advanced sharply in prices. French Beans are in request and selling at higher rates. Green vegetables are plentiful and at a moderate price level. The recent frost will curtail the crop of Scarlet Runners, and prices for this vegetable should advance. A few new Potatos from Guernsey are selling fairly freely.

SITUATIONS VACANT. *(Cont from page iii.)*

WANTED, YOUNG MAN with experience in the growing of Herbaceous and Alpines.—State full particulars of experience and age, J. W. FORSYTH, Putteridge Bury, Luton.

WANTED, experienced MAN for Pleasure Grounds, Herbaceous and Alpines, etc.; also strong LAD for general garden work; duty every third week.—Apply, stating age and wages, with good bothy, F. DAY, Whirlow Brook Gardens, near Sheffield.

WANTED, OUTSIDE FOREMAN; married or single; with experience, chiefly in Vegetables, Fruit, and the growing of Cut Flowers for market; must be well recommended.—State age, experience, etc., A. P. B., Box 32, 5, Tavistock Street, Covent Garden, W.C.2.

WANTED, strong, active JOURNEYMAN, experienced, for Pleasure Grounds; able to take duty every third week, paid; bothy, etc.—Wages and experience to H. WENMAN, Hickleton Gardens, Doncaster.

WANTED, for Sports Ground, Wembley district, a GROUNDSMAN; excellent opportunity for an energetic man; motor mowers.—Write, J. K., Box 21, 5, Tavistock Street, Covent Garden, W.C.2.

WANTED, MARRIED COUPLE; man experienced GARDENER, wife good plain COOK; part time in house; no children; three rooms; highest references essential; ages 35 to 40.—Reply, SIMPSON, Wynderoft, Enfield.

WANTED, a Young Man, about 25, single, as ODD MAN and fill up time in garden; wages 14/- per week, with board and lodging.—Apply, MISKIN, Woodseat, Rocester, Stafford.

TRADE.

GARDENERS.—Wanted, experienced Men for Jobbing and Landscape work. — THE HORTICULTURAL SUPPLY, Temple Fortune, Golders Green, N.W.11.

WANTED, GROWER for retail: Chrysanthemums, Bulbs and general cut stuff, bedding plants, etc.—State experience, references and wages required, JAMES NASH & SONS, Nurseries, East Horsley, Surrey.

LANDSCAPE and ROCK GARDEN FOREman, fully competent take levels and carry out all classes of work. State age, experience, wages and refs., P. S. L., Box 22, 5, Tavistock Street, Covent Garden, W.C.2.

WANTED, LANDSCAPE FOREMAN of good experience for contract work; must have good knowledge of Ornamentals.—Full particulars of experience, salary required, and copies of references, must be sent in first letter.—JOHN WATERER, SONS & CRISP, LIMITED, Twyford, Berks.

LANDSCAPE FOREMAN required, good all-round knowledge. — State full particulars and salary, H. W., Box 28, 5, Tavistock Street, Covent Garden, W.C.2.

VACANCY for PUPIL, up to date, modern Fruit Farm, General Nursery, glass, open-air pig rearing, poultry; packing and marketing produce; premium.—RYDER, Stratford-on-Avon.

YOUNG MAN wanted for Half-Hardy Department, with some experience in the propagation of Trees, Shrubs and Climbing Plants.—State full particulars and wages required, CLIBRANS, Altrincham.

TWO YOUNG MEN wanted for Roses, smart at budding and used to packing.—State wages and experience to THOS. ROBINSON, Porchester Nurseries, Nottingham.

WANTED, SEED TRADE, experienced SEEDSMAN, with thorough knowledge of all branches of the Agricultural Trade.—Send copies of references, with particulars of experience and wages required, to SECRETARY, c/o Toogood & Sons, Ltd., Southampton.

SEED TRADE.—Wanted, smart Young Man as SECOND SHOPMAN, with good counter experience and knowledge of high-class retail trade.—Copy testimonials, stating age, salary, etc., to W. DRUMMOND & SONS, LTD., Dawson Street, Dublin.

WANTED, JUNIOR ASSISTANT; used to Garden Seeds, Vegetables and Flowers, Bulbs and Sundries.—State age, experience, wages required, etc., to P. B. B., Box 30, 5, Tavistock Street, Garden, W.C.2.

COUNTER HAND required by large retail establishment; must have had first-class experience of the trade in all branches.—Apply, stating previous experience, wages required, age, etc., to K. C., Box 19, 5, Tavistock Street, Covent Garden, W.C.2.

WANTED, HEAD CLERK, capable of taking charge of office, Seed and Nursery house in West of England; progressive situation for the right man.—State experience, wages required, to CLERICUS, Box 14, 5, Tavistock Street, Covent Garden, W.C.2.

WANTED immediately, for Midlands, HEAD SHOPMAN with first-class experience in Seeds, etc., and well up in Floral work.—Apply, stating references, salary, etc. (in confidence), to MIDLANDS, Box 37, 5, Tavistock Street, Covent Garden, W.C.2.

WANTED, experienced ASSISTANT for our Cut Flower Department, solely for making up; one used to first-class work only; also able to take charge of the staff in the absence of Leading Hand.—Apply, WM. TRESEDER, LTD., The Nurseries, Cardiff.

WANTED, for first-class provincial shop, two YOUNG LADY FLORISTS, with good London experience in making up and counter trade.—Apply, stating experience and wages expected, with copies of references, to A. F. K. B., Box 44, 5, Tavistock Street, Covent Garden, W.C.2.

SITUATIONS WANTED

MUNICIPAL AND PUBLIC.

WANTED, situation as HEAD GARDENER in Public Gardens, or SUPERINTENDENT of Cemetery; experienced in the making and upkeep of Ornamental Grounds, Tennis Lawns, Herbaceous Borders, etc.; excellent testimonials; age 35.—Apply, F.R.H.S., Box 31, 5, Tavistock Street, Covent Garden, W.C.2.

PRIVATE.

COL. DARWIN, C.B., highly recommends his HEAD GARDENER where several are kept; life experience in all its branches in good establishments, including Dropmore Park, Buckinghamshire; twenty years Head with Col. Hanbury, C.M.G., Wexham Springs, Buckinghamshire; five years present situation; good references; married; leaving through closing establishment.—Apply, C. FROST, Elston Hall Gardens, Newark, Notts

HEAD GARDENER seeks re-engagement; practical life experience, Inside and Out, in good establishments; married; age 33; employer going abroad; cottage preferred.—STREET, Erigmore, Rogate, Petersfield, Hants.

GARDENER (HEAD) where several are kept; life experience, gained first-class establishments, England and America; good references, personal if required, from previous and present employers; married; age 32, available October 27.—A. WISE, Brooklands Cottage, Chobham, Surrey.

Agricultural Development and Unemployment.

The magnitude and persistence of unemployment in this country demand that every effort should be made to provide useful work. There are on foot and under consideration large schemes of road-making, electrification of railways and dock extension; but we do not remember having seen lately any pronouncement with respect to the putting on foot of agricultural or afforestation schemes for giving useful work to the unemployed. We are, of course, well aware of the many and serious difficulties which beset attempts to provide work of this kind in order to relieve unemployment. Among these difficulties are the inexperience of men whom it is sought to employ, the reluctance on the part of workmen accustomed to live and work in towns to go away from their homes, the problem of housing them in any considerable numbers and the poor output of work performed by persons when employed on tasks in which they have no or little practice. These and other serious difficulties are well known; yet the fact remains that on the one hand unemployment exists on a far larger scale than heretofore, and on the other hand there are many kinds of agricultural development which, could they be carried out, would be to the benefit of the nation and to agriculture. It is not for the layman to rush in where the angel administrator fears to tread, but it is, nevertheless, permissible to urge that all possible schemes calculated to give employment and result in permanent benefit to the land should be considered, not hurriedly in reply to urgent Cabinet demands, but well in advance of the time when such of them as seem most promising might be set on foot. It is, we believe, a fact that the Ministry of Agriculture has elaborate and detailed information as to schemes of land drainage and reclamation which, could they be carried out, would result in a large extension of the area under cultivation. The Forestry Commission has likewise given careful attention to schemes of afforestation. It is much to be desired that these schemes should be considered now—if it has not been done already—by a Cabinet Committee, which should include representatives of the several ministries concerned in the problem of unemployment, development of national resources and agriculture. It is said that the numbers of young men who have never been able to obtain work are very great, and it is recognised that to have a standing army of unemployed men—and particularly young men—is disastrous for the nation. Wherefore, in spite of the many difficulties well known to experts and administrators, which beset attempts to provide work of the kind we have in mind, we are certain that the attempt should be made—and that on a large scale. It is remarkable that in Germany—at all events those parts which have recently come under our observation—there is considerable activity in the direction of developing the natural resources of the land. It is true that the schemes of development appear to be carried out by skilled men and not by unemployed labour; but the fact remains that they are being carried out. With agriculture in its present depressed condition, it might seem idle to urge that steps should be taken to increase the area of land under cultivation; but at all events those who believe that world conditions will presently work for the betterment of agriculture—and we are among the number—will have no fear that more land under cultivation would mean a further embarrassment to the farmers. Beside the larger schemes of land drainage and reclamation there are other local schemes deserving of consideration which collectively would, if they could be operated, give no small amount of employment. But the main point to insist upon is that the possibilities of giving work to the unemployed on agricultural and forestry schemes should be once again reviewed whilst there is yet plenty of time to organise them.

Land Drainage Relief Work in 1922-23.—A brief but extremely interesting account of land drainage and similar work initiated by the Ministry of Agriculture and carried out by local authorities in 1922-23 is given in the *Journal of the Ministry of Agriculture* for September, 1923. Of six hundred and sixty-seven schemes for drainage, sea defence and water supply submitted for the sanction of the Ministry, five hundred and thirty-one were approved and carried out, providing employment for 1,018,976 man-days. The normal rate of wages paid was that for unskilled agricultural workers; the proportion of skilled to unskilled men was as one to ten. The expenditure amounted to £323,419, and the area benefited or protected from inundation was 912,738 acres. The work extended over nine months, from October, 1922, to June, 1923. It is particularly interesting to learn that the men—mainly ex-Service men—worked cheerfully and well, and that in spite of the fact that much of the work had, perforce, to be done under unpleasant conditions and was often of a distinctly unpleasant kind. Some idea of the value of the work done may be gathered from the illustrations which accompany the article: those showing the condition of rivers before cleansing indicate how necessary was the work of clearing them. No less encouraging is the fact that at all events in some cases the work was executed as effectively and as cheaply as it could be done at pre-war piece-work rates. As a result of these drainage undertakings over 2,000 miles of watercourses were cleared and over three-quarters of a million acres of land were benefited.

Insect Pests.—A Report from the Director of the Ministry of Agriculture's Pathological Laboratory at Harpenden refers to two years' work at the laboratory, and covers similar ground to the recently issued and corresponding Report dealing with fungous pests of plants. A few topics have been selected for detailed treatment, and among them that of Aphides injurious to fruit. This particular group of pests has been chosen, as it is one likely to be specially subject to weather conditions, and in consequence to illustrate the effects of the very different summers of 1920 and 1921. Other insects separately treated are cutworms, wire worms, Wheat bulb fly, frit fly, ear cockles, flea beetles, the Onion fly, the Cabbage white fly, and Cabbage aphis; in regard to fruit, the capsids, the bud weevil, the case bearers; and in regard to miscellaneous crops, the red spider, the Mustard beetle, the flower beetles, and the Willow beetles. The price of the publication is 2s. 6d. net, obtainable at the Office of the Ministry of Agriculture, 10, Whitehall Place, S.W.1.

Orchid Exhibitions at Westminster.—Referring to our paragraph on p. 214 dealing with the proposed exhibitions of specified genera of Orchids at the Royal Horticultural Hall, Westminster, Mr. James O'Brien writes: "I think the exhibition of special genera of Orchids in the manner indicated would be rendered doubly interesting if arrangements were made to show the pictures of all the members of each genus which have received awards at the Royal Horticultural Society. The pictures could be arranged together, and to avoid the necessity of handling them to see the records on the back, a small card with the name and parentage of each could be attached to the front of the picture."

A Large Peach.—Mr. Alfred T. Goodwin, Roseholme, Maidstone, informs us that on October 6 he gathered a fruit of Salway Peach weighing 16½ oz. In 1881 Mr. Goodwin gathered a fruit of Dr. Hogg Peach weighing 23¾ oz., as recorded in *Gard. Chron.*, August 27, 1881. Mr. Goodwin states that he gathered another fruit of Salway Peach, earlier in the same week, weighing 12½ oz., and that there are some large fruits still hanging on the tree.

The Canadian Apple Crop.—Whilst the crop of Apples in Canada this year is not quite equal to either that of 1921 or 1922, it is, nevertheless, a good one, and estimated at 3,376,000 barrels. British Columbia is the greatest Apple-producing district in Canada, the commercial crop in that province being estimated at 3,250,000 boxes, about 8 per cent. greater than last year's yield. Ontario and Nova Scotia are other large Apple-producing districts, and there is a fair quantity of Apples grown in Quebec and New Brunswick, but the yields in the last two provinces this year are much under those of 1922.

Silver Leaf Disease.—In April, 1919, the Ministry of Agriculture published a leaflet on Silver Leaf Disease in fruit trees, and the matter has been revised this autumn, giving the results of further research, although it is to be regretted that, according to the leaflet, no cure for Silver Leaf is at present known. The disease attacks other members of the Rosaceae than Plums, and is said to be particularly common on Apple, Almond, Apricot, Nectarine, Peach, Cherry, and Portugal Laurel.

Digitized by Google

It also affects trees and shrubs belonging to altogether different families, including the Currant, Gooseberry, Horse Chestnut, Laburnum, and Tree Lupin. Certain Plums are in a measure resistant to the disease, and varieties recommended for planting where Silver Leaf has been very severe are Pond's Seedling, Monarch, Purple Egg Plum, and Damsons, whilst Pershore Yellow Plum, River's Early Prolific, Blaisdon Red, and Damascene are seldom attacked. By the Silver Leaf Disease Order of 1923, occupiers of premises on which Plum and Apple trees are growing are required to cut off and destroy by fire on the premises all the dead wood on each Plum and Apple tree before July 15 of every year, and, where dead wood extends to the ground, the whole tree, including the roots, must be burned. The removal of diseased branches should be done at an early stage, and all wounds made by the removal of the branches should be pared over with a knife and covered with gas tar.

Dahlias in the United States.—The eighth annual exhibition of the American Dahlia Society was held on the 28th ult., on the roof garden of the Hotel Pennsylvania, New York. It appears that the exhibition was of unusual extent and brilliance, and the flowers were arranged in association with autumn-coloured foliage. The outstanding novelty was Jersey Beauty, a pink variety raised by Mr. W. H. Waite, to which a Gold Medal was awarded. We gather from an American contemporary that the American Dahlia Society has a membership of over 2,000, and it would appear that enthusiasm for the Dahlia is at present as great in the United States as it is in Holland.

American Honour for Mr. George Forrest, Collector.—All interested in horticulture will wish to congratulate Mr. George Forrest, the veteran plant collector, on his having lately been awarded the Robert White Medal for "Eminent Service in Horticulture." Mr. Forrest's labours in North China and Tibet now extend to some thirteen years of actual plant collecting, while the number of his Herbarium sheets runs into nearly twenty-four thousand. In this very large number it will readily be understood that many new genera and species are included, which are of special botanical and horticultural interest. To enumerate even a tithe of these would be impossible, but the record of our pages, and more recently published books, at once reveals the value of his work. Enthusiasts in the culture of the genera Rhododendron, Primula and Gentiana are well aware of the many beautiful additions he has made to the embellishment of their collections. Perhaps the full effect of Mr. Forrest's introductions will be more realised in the future, especially in regard to the trees and shrubs, when they have had time to develop. While congratulating Mr. Forrest on his being made the recipient of this honour, all who know him recognise it is well-deserved, and will wish him success in his next collecting trip, upon which he expects to start early in 1924.

Lakeland Beauty Spot for the Nation.—It is with very much pleasure we learn that the Fell and Rock Climbing Club of the English Lake District has presented to the nation about three thousand acres in one of the most beautiful parts of the English Lake District. This area will be placed under the control of the National Trust "for the use and enjoyment of the people of our land for all time," and is being presented as a war memorial to the twenty members of the club who lost their lives in the war. The beauty spot thus preserved for all time includes a large part of Scawfell, together with Kirkfell, Green Gable, the inner heights of Great Gable, Kern Knotts, Allen Crags and Seathwaite Fell.

"Gardening Illustrated."—We learn that Mr. W. P. Thomson, who for twenty-three years has been associated with *Gardening Illustrated*, and its editor for the greater part of that period, has relinquished the duties of editorship, which have been taken up by Mr. Herbert Cowley, formerly editor of *The Garden*. Mr. Cowley is an old Kewite, and since his retirement from *The Garden* he has been employed at Messrs. Wallace's nursery at Tunbridge Wells. He will still have the assistance of Mr. W. P. Thomson, who, we are glad to learn, is not entirely severing his connection with our contemporary.

Mr. W. H. Honess.—Mr. W. H. Honess, who has charge of Viscount St. Cyres' garden at Walhampton, in Hampshire, is a well-known member of the gardening fraternity, and although during recent years his visits to the Royal Horticultural Society's meetings have been much fewer, at the time he had charge of Cobham Park gardens he was present at almost all the fortnightly meetings, and his jovial personality secured him a host of friends. His career has been a varied one, for, after serving eighteen months in the seed department of Messrs. James Carter and Co., he commenced gardening proper at Aldenham House, Elstree, leaving there to become an apprentice in the gardens at Keele Hall, Staffordshire. How well he took advantage of his opportunities at Keele may be discovered from the fact that at the termination of his apprenticeship he was given charge of the fruit department, which at that time was one of considerable importance, as the late Mr. J. Wallis was a prominent exhibitor of fruit at important horticultural exhibitions. Mr. Honess left Keele to enter the gardens at Hatfield House, and later he served in the gardens at Welbeck Abbey at a time when extensive alterations were being made by the late Mr. Goldring, of Kew. The experience he gained at Welbeck in landscape work has been of great value to him. He left Welbeck to succeed his father as gardener at Cobham Park, Cobham. Here he remained for seven-and-a-half years, but, being offered the charge of Hopedene Gardens, Holmebury St. Mary, Dorking, where considerable and extensive alterations were about to be undertaken in the gardens, he left his father's old gardens, but, unfortunately, before the work at Hopedene was nearly completed, the estate was disposed of. Mr. Honess soon succeeded in obtaining a new appointment, this time in the service of Viscount St. Cyres at Walhampton, where he is at present. The Walhampton estate is situated between the New Forest and the shores of the Solent, and the gardens are so exceptionally favourably situated that many choice and semi-tender subjects succeed in them. It will be remembered that we have illustrated specimens of interesting plants from these gardens on one or two occasions, and it is hard to realise that such tender subjects as Solanum capsicastrum and Acacia dealbata will fruit and flower respectively so finely out-of-doors in this country. Mr. Honess informs us that they have excellent specimens in the open of such subjects as Eucalyptus cordata, E. globulus, E. Gunnii, Acacia Baileyana, A. dealbata, A. verticillata, Tricuspidaria Hookeri, Camellia reticulata, Fabiana imbricata, Grevillea rosmarinifolia, G. sulphurea, Dendromecon rigidum, Mitraria coccinea, Metrosideros lucida, M. speciosa, Abelia floribunda, Abutilon striatum, A. Milleri, Fuchsia Colensoi, Lachenalia bicolor, L. Nelsonii, and Cyclamen persicum. Both Viscount and Viscountess St. Cyres are keen gardeners, and throw their gardens open to the public on the first and third Sundays in the months of May, June, July, August and September, when collections are made for the local Cottage Hospital and the Gardeners' Royal Benevolent Institution, a method of helping charitable institutions which might well be copied by other owners of large gardens.

MR. W. H. HONESS.

Legacy to a Gardener.—The late Mrs. Mary Stewart Beattie Whitaker, of Broadclough Hall, Bacup, Lancashire, who died on July 18 last, bequeathed a sum of £300 to her gardener, Mr. Herbert Friend.

United Horticultural Benefit and Provident Society's Annual Dinner.—Sir William Lawrence, Bt., will preside at the annual dinner of the United Horticultural Benefit and Provident Society, which will be held at the Imperial Hotel, Russell Square, W.C., on Thursday, November 1. It is anticipated that a large number of members resident in the metropolitan area will be present, and we are asked to point out that lady relatives and friends of members will be welcomed at this function.

Seeds and Plants Imported into the United States in 1921.—The Bureau of Plant Industry of the U.S.A. Department of Agriculture has issued an *Inventory* of seeds and plants imported by the office of foreign seed and plant introductions during the period from January 1 to March 31, 1921. The booklet, with index, extends to ninety-two octavo pages and is extremely interesting, as a description is given of every plant imported, with notes of its usefulness and, in many cases, an indication of the part of the U.S. where it will grow. The introduction shows that during the period in question five hundred and forty-nine lots of plant immigrants reached Washington and were inspected, fumigated, labelled and planted in the various gardens of the Office of Foreign Seed and Plant Introduction. "Many come from all over the world, recommended for some particular purpose, and those which we were able to propagate will go out to the regions best suited to their culture and find their way into the hands of bona-fide plant experimenters, who will do something with them." The range is a wide one, as the plants include forest trees, forage and fodder plants, vegetables, nut-producing plants, dye and tannia plants, medicinal plants, fruits and plants for parks and "dooryards," the last including decorative subjects such as Paeonia lutea and Lemoine's hybrid Philadelphuses.

Black Heart of Potato.—The *Quarterly Bulletin* of the Agricultural Experiment Station, Michigan, describes and illustrates a complaint of Potato known as Black-heart. It is said to occur frequently in refrigerator-car shipments or in shipments where stoves cause overheating of the tubers. From the illustrations in the *Bulletin* Black-heart appears to be somewhat similar to the mysterious complaint known in this country as Sprain. The complaint is said to be brought about by lack of oxygen in the tuber, caused by the death of the cells around the lenticels or breathing pores of the Potato. As more and more cells are killed the discoloration extends. Black-heart is said to be common with pitted Potatos when the weather is excessively warm in spring. Affected tubers are a ready prey to saprophytic bacteria, which cause a foul-smelling rot of the tubers. The ventilation of Potato clamps and stores in which Potatos are wintered is recommended to counteract Black-heart, and it is also recommended not to pile Potatos in heaps more than five feet deep without making some provision for air to enter the centre of the pile.

A New Weed.—The Garlic-scented Pennycress, Thlaspi alliaceum, a native of South Europe and allied to Thlaspi arvense, the Pennycress, has made its appearance as a weed in this country. A note in the September number of the *Journal* of the Ministry of Agriculture records its appearance in an arable field near Ashford, Kent. Apparently the new-comer found its adopted home congenial, for in the month of May it was so numerous in a Corn field, which had not been ploughed owing to wet weather, as to look like a crop. It is a prolific annual, and moreover noxious, and should therefore be ousted from its position as a new weed.

Biology at Cambridge.—The Cambridge University Press has recently published for the Cambridge Philosophical Society the first number of a Biological Part of the *Proceedings* of the Society, which until now have contained, in a single series, mathematical, physicochemical, and biological papers. In separating the biological papers from the others it is hoped that a medium will be established for the publication of biological work of general interest carried out in the various departments of the University and possibly elsewhere. A Publication Committee, consisting of Professors and other representative biologists, has been appointed, and it is confidently expected that the standard of the papers will be up to that of the Society's other publications. It is proposed to issue the new *Proceedings* in quarterly numbers.

Appointments for the Ensuing Week.—Thursday, October 25: Royal Botanic Society's meeting; Wargrave and District Gardeners' Society's meeting. Friday, October 26: Imperial Fruit Show at Manchester (8 days).

"Gardeners' Chronicle" Seventy-five Years Ago.—*Gardeners' Labour Hours.*—At what hour of the day is it usual for the gardeners in your part of the country to begin their morning's work? My gentleman walks in about a quarter before eight, oftener eight, and by the time he has taken off his coat, opened his frame lights, and turned himself round, it is time to go to his breakfast, which he always brings with him; after sitting half an hour at this meal, and by the time he has taken out his tools, and again turned round, it is usually much nearer ten o'clock than half-past nine. Should I take so great a liberty as to hint my own opinion of the proper time of the morning at which I think a gardener ought to begin his work, and to which I have always in the north of England been accustomed, I am cut short with the remark, that "It is our custom here, and that he begins as early as other gardeners do." This latter part I believe. Then, again, my man takes his hour and half to dinner, having about ten minutes' walk to his house, and this too, I find, is the custom; for I see it practised almost daily by my neighbours' gardeners, who stroll home about half-past one o'clock, as if they were going to be put to the treadmill; so that very often it is on the eve of striking two when my man has put himself to rights, ready to begin to work. I do not know if this is the custom in your neighbourhood (with gardeners who get fair wages); but, if it is, I think it is a very bad one. *G. W.*—This is not the practice with industrious gardeners anywhere. Fix reasonable hours, and if they are not kept you have your remedy. *Gard. Chron., October* 14, 1848.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM BROTEHAM, BROADLANDS VARIETY.

The first flower of a seedling plant of this richly coloured hybrid between O. Lambardeanum (coeruleum × Vuylstekeae) and O. amabile (crispo-Harryanum × crispum) is sent by E. R. Ashton, Esq., Broadlands, Camden Park, Tunbridge Wells. It is of the same showy class as his O. Camden (Lambardeanum × Regale), and has the same velvety-purple tint. O. Pescatorei and a blotched O. crispum are the chief species employed in the production, with O. Harryanum and O. luteo-purpureum in some of the combinations. Examination of the species separately does not seem to disclose how such a heavily-coloured flower could result from their combination, but the thoughtful hybridist, by Nature's help, has accomplished many successes in colour and form, and thus the worker seldom misses his reward. The sepals and petals of the flower (Fig. 83) are bright violet-purple, with a slight white margin and tips. The crest is yellow and prominent; lip white with violet-purple base. *J. O'B.*

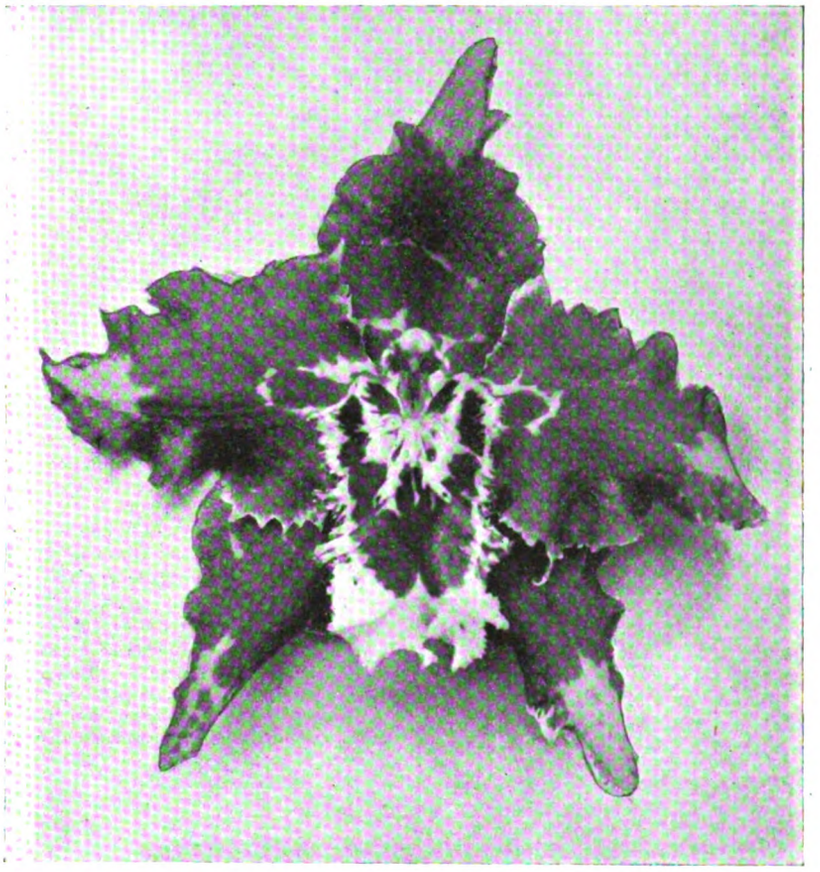

FIG. 83.—ODONTOGLOSSUM BROTEHAM, BROADLANDS VARIETY.

PHALAENOPSIS AMABILIS RIMESTADIANA.

This beautiful pure white Orchid is well in bloom in Messrs. Charlesworth and Co.'s nurseries, Haywards Heath, and some fine specimens of it were shown in the Gold Medal group of this firm at Holland Park Hall on October 2. The species is widely distributed in Malaya. Its complicated history was well set forth by the late Mr. R. A. Rolfe in the *Gardeners' Chronicle*, 1886, p. 168. The same variety, at first known as P. grandiflora, Lindl., and on the more recent importation as P. Rimestadiana, is the largest flowered, and best form of the species, and, moreover, it is the easiest to cultivate, as it has frequently been successfully grown in an ordinary warm house, in association with stove flowering and foliage plants. It is one of the fine species which growers should render plentiful in gardens by raising a batch of seedlings, a matter that is not difficult; seedling plants grow better than those imported, and importation in the present day is difficult and expensive.

LAELIO-CATTLEYA ROSY MORN.

Cattleya Armstrongiae (Hardyana × Loddigesii) raised and flowered by Messrs. Armstrong and Brown in 1907, was one of the brightest and most florally perfect of its class, and it is much appreciated by growers for cut flowers and decoration. In crossing it with Laelio-Cattleya Olivia (C. Schroderae × L. Jongheana) all the good qualities of C. Armstrongiae have been retained in an enlarged and improved degree. The flower of L.-C. Rosy Morn is a model of floral excellence. The sepals and very broad petals are bright magenta rose. The lip is bright yellow with an orange shade in the centre shading to pink in front.

Other new forms of Orchidhurst hybrids sent include Cattleya Achine Orchidhurst variety like a good white C. Mendelii with a purple blotch on the lip; C. Snowcap (Claesiana alba × Saturn alba), a good white and the remarkably beautiful Odontoglossum Dictune, Orchidhurst variety, the heavily coloured flower having opaque blotches of silver-white.

LAELIO-CATTLEYA BARON COFFINET.

With other novelties Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, send a flower of this noble cross with Cattleya Hardyana, the newcomer taking a prominent place in the class of large-flowered yellow-petalled Laelio-Cattleyas, besides being a valuable addition to the winter-flowering section. The sepals and petals, which extend to nearly eight inches in width and are of firm substance, are light Cowslip-yellow, with a delicate tracery along the veining. The broad lip is Tyrian purple, darker in the centre and with delicate gold lines at the base.

The Week's Work.

THE ORCHID HOUSES.

By J. T. Barker, late Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

Oncidium Kramerianum and O. Papilio.—These two warm house Oncidiums are highly appreciated when in bloom, their butterfly-like flowers being very attractive and interesting, although not produced in such profusion as in the case of some other species. The plants continue to produce fresh flowers from each stem for a considerable period, but it is wise to remove the spikes after they have produced a reasonable quantity of flowers. These beautiful Oncidiums prefer a light position, and should be grown in small pans suspended close to the roof glass; they need only a small quantity of material to root in, which should be kept moderately moist at all seasons. The smallest possible receptacles should be used for their accommodation, and careful watering is essential until the plants are thoroughly established.

Zygopetalum maxillare.—When well grown, Zygopetalum maxillare is a most desirable Orchid, and several fine hybrids have been raised from it. There are good and bad varieties of this plant; the lip in the best varieties is of a rich violet-blue, which makes a strong contrast against the green and brown of the sepals and petals. In its native habitat this plant grows on the stems of Tree Ferns, and it is instructive to note that it mostly grows in subdued light, owing to the spreading fronds of the Fern. In view of the natural rooting-medium of the plant, it is advisable to provide an open rooting material, such as well cleaned Osmunda fibre affords. Many cultivators grow this plant attached to a piece of Tree Fern, plunged in a pot, so that its roots eventually run down the stem into the compost below. The plant does best in a shady position in the warm intermediate house, and should never be allowed to become excessively dry at the roots. Both the leaves and the stems should be sprayed lightly overhead on all favourable occasions, even during the winter.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to J. A. Brenners, Esq., Woolverstone Park Gardens, Ipswich.

Strawberries in Pots.—Afford the plants plenty of room to allow sunshine and air to circulate freely about them in order that the crowns may be fully developed by the end of the autumn. The earliest potted plants—where the pots are well filled with roots—will be benefited by occasional waterings with liquid manure and soot-water. Keep the plants free from weeds and decayed foliage, remove all runners and side growths as they appear, and guard against dryness at the roots, but at the same time give only sufficient water to satisfy the plants' needs, just keeping the soil in a moist condition. To ward off attacks of red spider or mildew, syringe or dip the plants in a solution of soft soap and sulphide of potassium, at a strength of half an ounce of the sulphide to one gallon of water; the soapy mixture should be stirred thoroughly before use. If worms are troublesome in the soil they may be eradicated by using clear lime-water.

The Early Vinery.—The early vinery is generally utilised for plant storage up to the latest time when it must be cleared to make preparations for starting the vines. If it is possible to undertake the work at the present time so much the better, as it will be necessary to start the vines towards the end of November if ripe Grapes are required by April next. If the vines have not yet been pruned, shorten the laterals to two or three buds. If the basal buds appear to be of doubtful quality, leave three, but if they are well plumped up two buds will be sufficient. In the former case, should the basal bud break satisfactorily, and show a bunch, the other shoots may be rubbed off. When shortening the leading growth of a young rod, it is a good plan to leave an extra bud, for the reason that such a bud usually starts into growth sooner than the lower buds, and will, if allowed to take the lead, cause the lower buds to break weakly and irregularly. If an extra bud is left, and allowed to make a growth of 2 or 3 inches, and then rubbed off, it gives a slight check to the sap, and causes the lower buds to break in a more even manner. Early-forced vines are more liable to bleed than late ones, owing to the resting period being considerably curtailed. If the vines are free of insect pests, it is not advisable to strip off the outer bark too closely; merely remove the loose portions, which may be readily detached from the rod. Should, however, the vines be infested with mealy bug or red spider, it will be necessary to remove the bark, which is likely to be a hiding place for these pests. Cyaniding is the most successful method of eradicating mealy bug, but many do not care to resort to cyaniding, on the score of its danger to the operator, yet if the directions given for use are followed carefully, the operation will be free from danger. Those who prefer to use other methods will find Gishurst's compound, or paraffin emulsion suitable for the purpose; these specifics will also destroy red spider. The glass and woodwork of the house should be thoroughly cleansed, and the walls limewashed. All crevices in the ironwork, which support the wires, should be painted with paraffin, and the ventilating gear well oiled. An inch or two of the surface soil of the border should be removed, substituting turfy loam, freely mixed with the old plaster and wood-ash. If the border requires enriching, artificial manure may be added to the top-dressing material. Admit air freely up to the time of closing the house. If the border is outside material for a hotbed should be prepared and placed thereon when the vines are started. To retain the heat of the hotbed it is desirable to cover it with spare lights, wood shutters, or any other suitable means of warding off rain and snow.

THE KITCHEN GARDEN.

By R. W. Thatcher, Gardener to Mark Firth, Esq., Carlton Park, Market Harborough, Leicestershire.

Rhubarb.—A few crowns of an early maturing variety of Rhubarb may be lifted and placed in a dark shed or Mushroom house, in which they will soon commence to grow, and the stalks will prove useful about Christmas. Forced Rhubarb will be especially valuable this season, as the crop of Apples is a small one. Place sufficient old potting soil over the roots to cover them, press it moderately firm, and then water the roots copiously.

Late Potatos.—The late Potato crop should be dug as soon as possible, as the tubers may deteriorate if left in the ground longer, whilst a sharp frost would hinder lifting operations, and possibly damage the tubers. The haulm should all be cut off, and cleared away before digging commences. The tubers will then dry better on the surface before they are stored. Examine the crop as it is dug, and throw out any tubers that are diseased, and burn them. Late Potatos will keep quite well out-of-doors in a clamp, on slightly raised ground. Make a cone-shaped heap of the tubers, and then cover them with plenty of straw. Dig a trench all round the clamp, and bank the latter with soil up to nearly the top. The unsoiled part will admit the air freely and allow the tubers to become thoroughly dry. In case of severe frost, cover the heap with a good thickness of long litter or dried Bracken Fern.

Lettuces.—Lettuces are doing well out-of-doors this autumn, no doubt owing to the frequent rains and warm weather. From now onwards the young plants should be lifted and placed in cold frames, the lights of which should be placed in position at night. Keep the soil well stirred between the plants and water them freely in the morning, when they need moisture. These Lettuces will prove valuable for use as salad and other purposes.

HARDY FRUIT GARDEN.

By A. J. Hartless, Gardener to Major J. F. Harrison, King's Walden Bury, Hitchin, Hertfordshire.

Insect Pests.—Another pest besides the winter moth may be dealt with during October. To kill Apple suckers, or Apple chermes, as they are sometimes called, before they lay their eggs in the autumn is far better than dealing with the young hatched in spring. Certain districts are more troubled with this pest than others. Usually at this time of the year one notices the chermes flying about rapidly if disturbed; they vary in colour from green to yellowish. Paraffin emulsion is a good insecticide to use against these tiny insects. The harm they do in sucking the sap from the fruit blossoms, and the injury they cause, may go on quite unsuspected until the withering of the latter may be evident, and sometimes, if the attack is a severe one, cause a browning of the petals similar to the effect of frost.

Application of Manures.—A general application of basic slag may be desirable in large fruit orchards. This fertiliser will assist both trees and bushes, and a dressing of 4 ounces to 8 ounces per square yard may be applied and hoed or lightly forked in the soil.

Fruit Cuttings.—Cuttings of Gooseberries, Currants, Loganberries and Brambles of sorts may now be inserted. The cuttings should be inserted in the soil about two-thirds their depth, 1 foot apart, in a trench, the bottom of which should be made firm and sprinkled with sand. Place the cuttings on one side of the trench, which should be cut perfectly straight, and make them firm with the foot when filling in the soil. Care should be taken to select only well ripened shoots for making cuttings. The lower buds of Red Currant shoots should be rubbed off to obtain a clear stem or leg. Gooseberries may be treated in the same way. The Lowberry, like the Loganberry, will become extensively cultivated when it becomes better known.

Transplanting.—This work may now be commenced, especially where the soil is moist. Every care should be taken not to damage the fibrous roots; any that have been bruised should have the damaged portion cut off cleanly with a sharp knife. Keep the roots as near the surface of the soil as possible, and make quite sure that they rest on a firm base. This can only be done by well firming the soil with a wooden rammer. Firm planting is especially important in the case of cordon trees. It is a good plan, especially when planting large trees, to fill in two-thirds of the soil, and after ramming the latter to give each tree a thorough soaking of water. When this has soaked away the remainder of the soil may be placed in position. In view of autumn gales, an occasional inspection should be made of wall trees, and any ties that are broken should be immediately replaced by sound ones.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Gladiolus.—Gladioli of the nanus and ramosus sections, in their many fine varieties, are excellent subjects for cultivation in pots, either for conservatory decoration or for providing a supply of cut flower. They should be potted up during October, and as they are free-rooting plants they require fairly large pots; five or six corms should be put in a 7-inch pot. Many cultivators use pots of insufficient size, with the result that the plants are starved and lose their foliage. After potting they may be stood in cold frames, or out of doors at the foot of a wall, covering the pots with ashes, and allowing them to remain covered until the plants are well rooted and commencing to grow, when they should be transferred to cold frames. Where they are required in quantity for a supply of cut flowers they may be planted in boxes in cold frames. G. Colvillei and its white variety, generally known as "The Bride," are largely grown for market purposes, and are worthy of more general attention from the

Digitized by Google

private grower. There are many other fine varieties, viz., Fire King, Apple Blossom, Blushing Bride, Ne-Plus-Ultra, Sappho, Ackermannii, and Rose Queen.

Ixias.—In their many fine varieties Ixias are suited for the decoration of the greenhouse, and are ideal for giving a supply of cut flowers over a long period. Once great favourites, they are now seldom seen, and this is surprising considering how cheap the corms are, while their cultural requirements are of the simplest. As their corms are small, six or eight may be placed in a 5-inch pot, afterwards standing them in a cold frame, where they may remain until they throw up their flower spikes, when they should be removed to a cool, airy greenhouse. In short, they may be given exactly the same treatment as Freesias, growing them perfectly cool at all times. In the south they may be planted outdoors in a border of light soil at the foot of a warm wall, although during severe weather it may be necessary to give them some slight protection.

Babiana.—The Babianas are beautiful South African bulbous plants, which should be more generally cultivated. They succeed under the same treatment as that indicated for Ixias, and are very useful for the small, unheated greenhouse.

THE FLOWER GARDEN.

By C. Turner, Gardener to Emily, Lady Ampthill, Ampthill Park, Ampthill, Bedfordshire.

Spring Bedding.—Any part of the garden to be replenished with spring flowering plants should receive attention now before the soil gets too wet and cold with the autumn rains. Where bulbs are to be used in association with foliage plants, but are not to hand at the time, due allowance must be made for adding them afterwards. Early November is the best time for planting Tulips, while October is the ideal time for planting Hyacinths. Daffodils used for spring bedding should be planted forthwith if convenient to do so, for although they may be planted fairly successfully so late as mid-December, the earlier plantings give the best result and flower sooner.

Lilium.—With the exception of L. candidum—which I have dealt with in a previous calendar—the bulbs of Lilies are not, as a rule, available for planting before the end of October or early November. In making fresh groupings of Lilies choose a portion of ground that is well drained. The soil should be loosened to a good depth, and if of poor quality enriched with well-rotted manure and leaf-mould. Sand placed under and around the bulbs will serve to keep them drier when moisture is excessive, and is to be particularly recommended where the soil is on the heavy side. Temporary shading from the hot sunshine is also desirable. This may usually be provided by planting the bulbs between shrubs, near pergolas, or where a tree or tall-growing plant casts shade during the hottest period of the day. A few strong growing Lilies are:—L. canadense, L. chalcedonicum, L. croceum, L. elegans, L. Henryi, L. Martagon, L. pardalinum, L. testaceum and L. tigrinum. Stem-rooting species, such as L. Henryi, require earthing up with good soil as soon as the roots appear. L. pardalinum should be planted in almost complete shade. A bed or group of evergreens that is not crowded is a capital place to plant bulbs of various Lilies.

Fallen Leaves.—Where deciduous trees predominate in pleasure grounds, as they do here, the work of sweeping and collecting the fallen leaves involve considerable labour at this season. The leaves should be placed in one or two large heaps in a place where they are not likely to be blown on to the lawns again. Failing such an out-of-the-way place in the shrubbery they may be placed in a large hole dug for the purpose, laying some evergreen branches over the top when the work is complete. Leaves likely to be wanted later for the making of hot-beds should be placed elsewhere, and not mixed with those stacked to decay and form leaf-mould, such as those of Oak or Beech.

TREES AND SHRUBS.

GAULTHERIA PROCUMBENS.

This is a pretty little peat-loving shrub of the Ericaceous order, a native of the Eastern States of America, and introduced 150 years ago. It is popularly known as the Creeping Wintergreen, or Partridge Berry, and it has long been valued for the "oil of winter-green" extracted from its fruits and used by chemists for the flavouring of drugs and other purposes. A leaf crushed between the fingers at once reveals the familiar odour of that extract. G. procumbens is a charming subject for cool, shady places where it may be used for associating with other lowly plants of a like nature, or for carpeting the ground about dwarf Azaleas. It does not often exceed 6 inches in stature, and is usually not much more than half that height, the little tufts of leathery, dark green leaves being borne on erect stems, which rise from the creeping roots. The almost cylindrical flowers, which appear in clusters at the leaf-axils in late summer and autumn, are large enough to be conspicuous and of a fresh pinky-white. These are followed by berries as large as those of the Holly and of much the same colour. This is, perhaps, the easiest of the smaller Gaultherias to satisfy. It does well in lime-free loam and leaf-mould. *N. Wales.*

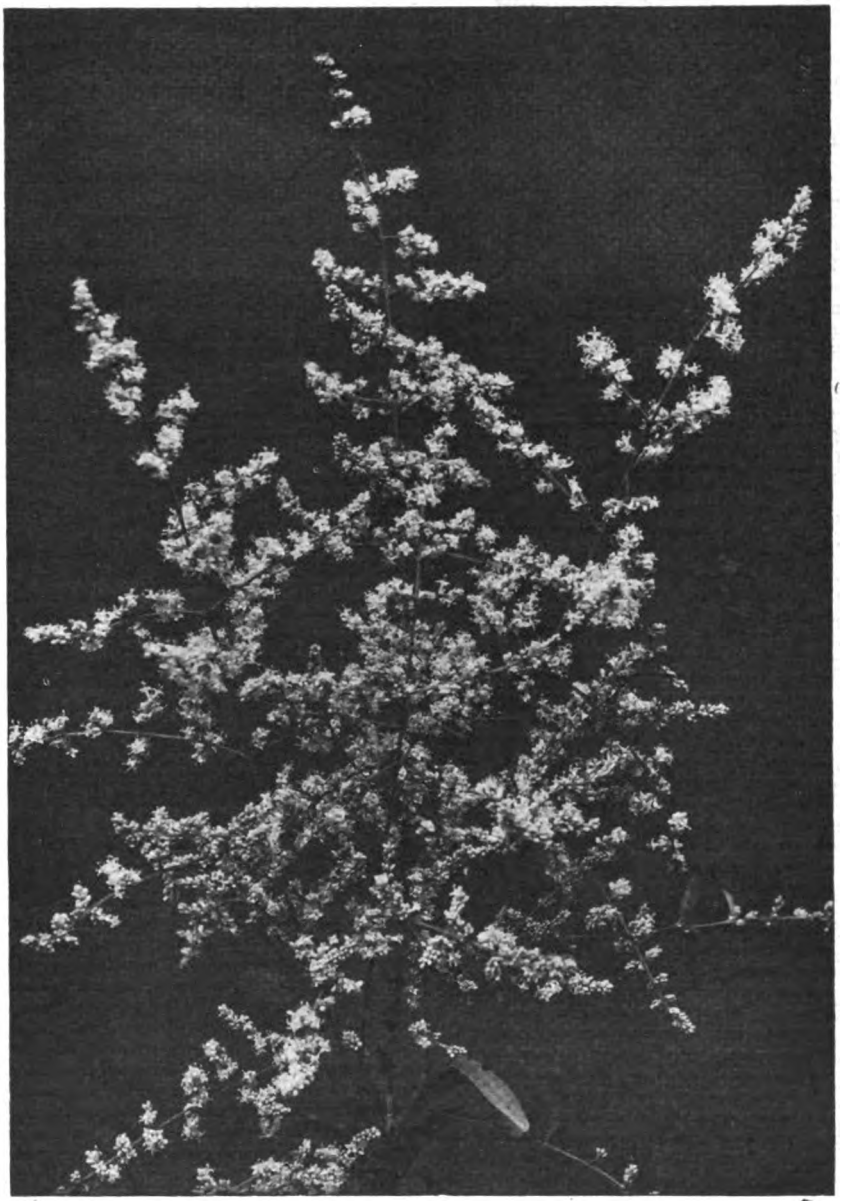

FIG. 84.—LIGUSTRUM QUIHOUI, R.H.S. AWARD OF MERIT, HOLLAND PARK SHOW, OCTOBER 2 (SEE PAGE 208).

PAULOWNIA IMPERIALIS.

There is an interesting specimen of Paulownia imperialis at Tongres in the province of Limbourg, Belgium. It is in the Club grounds of the Société Royale de Musique. The height, about 35 feet, is not exceptional, but the circumference of the trunk measured at 6 feet from ground level is 10 feet 3½ inches. The main portion of the trunk appears to be perfectly sound; it divides at about 12 feet high into two main branches; a third branch was broken off some years ago and the wound has partly healed over. Several of the smaller branches exhibit signs of decay. From the fork of the main branches two young Mountain Ash trees are growing, one 2 feet and the other 6 feet high. *Alfred B. Melles, Ypres.*

PINUS SYLVESTRIS AUREA.

This is a form of the Scotch Pine which is seldom seen in gardens, yet it is a subject of much merit and distinction. It is a very slow grower—practically a dwarf—but its most remarkable feature is the rich golden or brassy colour which the leaves assume in late autumn and which is retained throughout the winter.

P. sylvestris aurea is an admirable subject for the rock garden, or collection of dwarf Conifers. *A. T. J.*

AUTUMN TINTS.

THE colouration of foliage in autumn is usually much more highly developed on poor soils than on rich soils, hence when planting with a view to the production of autumn tints soils of moderate richness only are to be preferred. Amongst trees, one of the best and most certain for colour is the variety of the American Red Oak known as Quercus coccinea splendens, as, not only does the foliage turn to a very fine crimson, but the tree retains its brilliant foliage for a long period. Liquidambar styraciflua is also highly valued for its brilliant scarlet and orange-scarlet colour, and Gleditschia triacanthos for its beautiful golden yellow tones. Amelanchier canadensis is usually one of the first to change colour, the edge of the leaf becoming bronzed as early as August. This deepens into red and gradually spreads through the whole leaf until the greater portion is crimson, the remaining part lighting up with yellow and orange shades.

There are several Acers, notably A. Ginnala, A. Schwedleri, and A. japonica, which turn to various shades of red and scarlet.

Other trees that deserve mention are Crataegus Crus-galli, brilliant scarlet and gold; Pyrus torminalis, bronzy red; Parrotia persica, red and yellow, and the common Horse Chestnut, Æsculus Hippocastanum, which turns to a beautiful golden yellow tinged with bronze. Amongst shrubs the Sumachs furnish some of the most striking autumn tints. Rhus cotinoides, R. glabra and R. Toxicodendron all turn brilliant crimson, orange and scarlet, whilst R. Cotinus becomes a rich golden yellow. The foliage of Berberis Thunbergii dies off a rich scarlet, and is most effective, whilst its evergreen ally, B. Aquifolium, turns a glowing red and purple after the first frost. Enkianthus japonicus develops a rich, fiery red, and should be included in any planting scheme for autumn tints.

Our native Guelder Rose, the common Viburnum Opulus, becomes a deep crimson in autumn, whilst the common Hazel produces fine effects in yellow. Spiraea Thunbergii, with its feathery foliage, provides a beautiful study in crimson, and the blazing scarlet of Vaccinium pennsylvanicum is not easily forgotten. The Ghent and Mollis Azaleas usually colour freely and give a rich combination of crimson, scarlet and gold.

In a planting scheme for autumn colour effect the value of Gaultheria procumbens as an edging plant or for undergrowths should not be overlooked. Its beautiful crimson-stained leaves remain effective during the whole autumn and early winter. As the causes effecting the changes in the colour of leaves in autumn are largely controlled by light, temperature and moisture, the degree of colouration even in the same subjects varies considerably from year to year. Further, it frequently happens that young plants make vigorous, sappy growth, the leaves of which fail to take on their autumn colours, whereas the same plants when older and less vigorous in growth are conspicuous for their highly developed tints. *W. Auton.*

HOLLAND IN AUTUMN.

(*Concluded from p.* 215.)

ONE very interesting day was spent at Boskoop. In the early morning visitors journeyed from Amsterdam to Gouda, and thence proceeded by steamer up one of the arms of the Rhine to Boskoop. Arriving at Boskoop, the party to which we were attached proceeded by motor launch to the nurseries of Messrs. H. den Ouden and Son, then walked back through this extensive place, in which Rhododendrons are grown splendidly in extraordinary numbers, chiefly for export. Other special subjects in this establishment are flowering Cherries, shrubby Spiraeas, Berberis, Privet, Lilacs and Viburnums. Mollis and Ghent Azaleas are a great feature, and excellent stocks were noticed of Rhododendron racemosum and R. praecox, Picea Breweriana, P. pungens Moerheimii, Cotoneaster lanata, Taxus cuspidata, Cedrus atlantica glauca and the rarer Ilex Pernyi. In the section devoted to herbaceous plants there were fine collections of perennial Asters, Phloxes (75,000)—which were blooming profusely; Irises, including all the new varieties obtainable; Potentillas, Crinums, Geums, Veronicas, Astilbes, Pyrethrums, Salvia nemorosa, and Gypsophila repens rosea. The collection of hardy flowers is a particularly extensive one, and all the leading varieties of popular border flowers are represented.

At this season of the year the bulb-growing district around Haarlem is not particularly attractive, but it was interesting because the planting of bulbs was in progress. Opportunity was afforded for a visit to Lisse and an all too brief inspection of the school where all potential bulb growers have an opportunity of a thorough education in all branches of that industry.

Even more brief was the opportunity of inspecting the State laboratory where all diseases and pests which attack bulbs are investigated by Dr. van Slogteren and his staff. Here also the interesting subject of preparing bulbs for forcing is tested in many ways, and here again, probably for the first time, many visitors saw the dread Daffodil eelworm—under the microscope.

Attention has been drawn elsewhere to the wonderful popularity of the Dahlia in Holland, but another autumn flower which is extensively grown both in private gardens and for market is the Gladiolus, and in the bulb-growing district one may see acres of such popular varieties as Halley, Giant White and America.

Altogether it must be admitted that a brief visit to Holland in the autumn may be as full of interest and of educational value as one made in the springtime, when so many British horticulturists visit the Netherlands for the purpose of inspecting Tulips, Daffodils, Hyacinths, Crocuses and the other bulbous plants which present such extraordinary patches of colour and, indeed, provide the chief attraction in the flat landscape. *C. H. C.*

INDOOR PLANTS.

FICUS.

MANY species of Ficus are useful for different kinds of indoor decorations, altogether distinct from the well-known Fig (Ficus Carica), which is cultivated for its fruit alone. There are trailing and climbing species, and ornamental foliaged kinds. The scandant trailing species can hardly be surpassed as trailers or creepers for covering walls and other bare spaces in ordinary warm greenhouses or conservatories. They are also most suitable for growing in baskets suspended from the roof rafters. They make rapid growth, and may be grown without difficulty in a border against a wall for covering the same. They will cling to the wall similar to Ampelopsis Veitchii, with the advantage of being evergreen, so that the wall is hidden throughout the year.

They also make useful plants for draping the front of the plant stages, the growth hanging down in festoons some 2 feet to 3 feet, and hiding the unsightly bare spaces under the stage.

Other species are grown for their ornamental foliage as decorative plants in the greenhouse and conservatory, and are especially useful for placing in large halls and apartments.

The following are the best of the creeping or trailing kinds:—F. radicans, one of the most useful for covering walls and other bare spaces, on account of its neat, bright green foliage. The leaves are placed alternately along slender shoots, and opposite each leaf numerous rootlets develop by which the plant clings to the surface over which it spreads. It is an extremely useful plant for use as an edging to stages, also a splendid subject for growing in hanging baskets.

Ficus radicans variegata has beautiful variegated foliage; in some leaves the variegation is marginal, and in others nearly the whole surface is coloured creamy white, which makes the plant very attractive when grown in suspended baskets or in places where the shoots are allowed to droop naturally. When intermixed with other foliage its effect is very striking. Baskets tastefully filled with this variegated Ficus and suspended from the roof-rafters are very ornamental and serve to make the conservatory bright and gay.

Unfortunately sufficient attention is not paid to the culture of plants in suspended baskets; many object to the trouble in taking them down for watering and other necessary attention that they may require from time to time. Ornamental wire baskets are the best, and before putting the soil in the baskets they should be well lined with Moss. F. repens (syn. stipulata), is a very neat-growing variety, with smaller foliage than F. radicans, but requiring similar treatment. This is a great favourite for covering walls of conservatories and other plant houses. The leaves are close, small, and thin, and the plant makes a dense mat of foliage, which is as dark in colour as the English Ivy. The stems are slender, and adhere to the wall by little rootlets. Occasionally the plant develops fruits; the fruiting branches are very unlike the juvenile growths: they stand out from the wall instead of lying close and flat against it.

F. repens minima is a unique plant, with dense, small, bright green foliage. It is very neat and compact in habit. The shoots cling readily against a damp wall, or any rough material. This species is invaluable as a carpeting plant of vivid green, and is useful for covering rockeries, forming mossy carpets of greenery.

All the creeping species and varieties of the genus Ficus may be increased readily from cuttings formed of half-ripened shoots and placed in moderate warmth with plenty of moisture in the atmosphere. They should be grown in a winter temperature of 45° to 50°, and need shading from bright sunshine in summer.

F. elastica (the India-rubber plant) is grown extensively as a decorative plant for the greenhouse, or cool conservatory, and is especially useful for standing in halls and dwelling rooms. It makes a good foliage plant for associating in mixed beds in the flower garden from June to the end of September. The plant is liable to drop its foliage if it is over-potted. For propagation select old, bushy, stock plants, and place them in a house having a night temperature of 60° to 65°. As soon as the shoots are 5 inches to 6 inches long they should be taken off, inserted singly in small pots containing sandy soil, and rooted under a hand light, in a temperature about 70°.

During the warm summer season the plants may be grown in frames or pits slightly shaded from the sun. F. elastica variegata is an attractive variety, the leaves being striped and marked with creamy white. F. Parcellii is a splendid decorative plant for a warm conservatory; it has beautifully variegated foliage. The leaves are of large size, thin in texture, and mottled profusely with creamy white and dark green. Ficus eburnea is a handsome, ornamental plant requiring a warm temperature. It produces leaves 12 inches to 15 inches long and 9 inches wide. *John Heal, V.M.H.*

PSEUDERANTHEMUM SETICALYX.

THIS indoor flowering plant is usually afforded stove house treatment, but this is not necessary, as it may be grown in an ordinary greenhouse, or even in a cold frame during the summer, provided the light is closed early in the afternoons, to trap plenty of sun heat. In common with most indoor Acanthads, this plant is easily propagated at any time by means of cuttings of the young shoots. But good plants for flowering at this season may be raised from cuttings inserted during April in a close case with slight bottom heat. The points of growth should be pinched two or three times to induce a bushy habit. *C.*

IRISES.

IRIS PUMILA.

The note on Iris pumila on p. 218 is somewhat misleading and seems to confuse this species with at least two or three others, namely, I. Chamaeiris, I. aphylla and I. mellita.

The large-flowered dwarf Iris from Southern Europe is, of course, I. Chamaeiris, the species which nearly always represents I. pumila among trade growers. Neither I. Chamaeiris nor I. pumila occurs in Asia Minor, where another dwarf species, I. mellita, is found. This is stemless, as is also the true I. pumila, but it differs from I. pumila in having boat-shaped, green spathes with a sharp keel instead of the closely wrapped, shapeless and almost colourless spathes of I. pumila. I. Chamaeiris comes from the South of France and North Italy, while I. pumila is confined to Austria, Hungary, the Croatian Coast, Greece, the Crimea and other parts of Southern Russia. The flower is relatively small and always rather crumpled. The colour is most variable, and in some places, as, for instance, on the Geissberg outside Vienna and near Weisskirchen in Moravia, each individual plant is of a different colour. The so-called I. pumila coerulea is not a true pumila but a garden hybrid, probably with I. Chamaeiris. I. gracilis (or I. cinerea) is neither a pumila nor a Chamaeiris, but a colour variety of one of the many local forms of the Central European I. aphylla.

Anyone who has once seen the seed vessels of the real I. pumila sitting absolutely on the ground at the base of the leaves, with the long slender perianth tube and withered flower still attached to its apex, will never be likely again to confuse this species with I. Chamaeiris. It is the long perianth tube above the ovary that raises the flowers of I. pumila four or six inches above the ground. It is extremely rare to find any stem at all, and even then it is shorter than the perianth tube. *W. R. Dykes.*

HARDY FLOWER BORDER.

HOLLYHOCKS.

I desire to call attention to the great decorative value of Hollyhocks when arranged in large masses? Usually, probably invariably, Hollyhocks are planted singly or in groups of from three to ten or so, but what I suggest is a group or groups covering 100 square yards. Where there is space for a group covering that extent, with a suitable background, the idea should be carried out. I have grown single varieties only in this way, the selected offspring of a hybrid race between Althaea rosea, A. ficifolia and another, and their beauty has been very satisfying. In the north seeds should be sown in autumn rather than in spring, in order to secure strong, healthy flowering plants to put out in February or March, for I find these—probably from the infusion of a Siberian species—to be practically hardy. They are also less liable to disease than the common strains. I would like to state that it may be best not to grow the Hollyhocks in highly manured ground. They grow quite tall enough in ordinarily fertile soil, and are practically perennial therein. *R. P. Brotherston.*

EARLY SINGLE CHRYSANTHEMUM.

Being an old exhibitor and lover of the Chrysanthemum, my garden generally contains a few of the best early flowering sorts; but among these not one has appealed to me so much as a variety named Shrapnel. The colour, somewhat like that of Mary Richardson, is sometimes described as orange terra-cotta. The flowers are large, and freely produced, the habit of the plant being similar to that of Roi des Blancs. I find Shrapnel responds to liberal supplies of liquid manure. Dolly Thorpe, a pleasing salmon-apricot shade, is much to my liking, and a good cropper, useful and charming for vase and table decoration. Salmonia, a bicolor variety, is also very pleasing and useful, the flowers being large and borne in good sprays. *G. L.*

THE ROSE GARDEN.

SOME GOOD BEDDING ROSES.

It has been my pleasure to live more or less near ten acres of Roses, and I have had ample opportunity for watching the behaviour of the different varieties grown. The following are all free-growing and also free-flowering varieties, rendering them useful for the garden and also for cut flower purposes.

Golden Emblem is a variety of great charm and is one of the three best yellow garden Roses. The growth is robust, the flowers are large and strongly perfumed, making Golden Emblem an ideal Rose in every respect.

Christine (see Fig. 85) is a splendid yellow Rose and mildew-proof; this is a splendid variety for the Rose garden.

FIG. 85.—ROSE CHRISTINE.

Mabel Morse is a variety of recent introduction with a free habit of growth. The flowers are large, well formed and produced continuously. The foliage is mildew-proof.

Independance Day is a Rose of great charm, the colour being of exquisite tinting, orange-apricot and Sunflower gold, with flame-coloured stains making the whole an enchantment of colour. The growth is free and the flowering period lengthy.

Sunstar is one of the most beautiful of all Roses and is splendid both in its growth and flowering. The scent of this variety is delicious. The colour is orange, edged and veined with vermilion.

Ophelia as a bedder is unsurpassed in its colour, which is salmon-flesh, shaded rose. The flowers are freely produced all the season, and, to my mind, of a richer hue in the autumn. The blooms are fragrant and carried on upright stems. Red Letter Day is a free-blooming Rose with a deep, rich colour which does not readily fade to magenta. It is a Rose to be commended, for its blossoms are continuously and freely produced.

Gorgeous is a large, handsome variety with a strong perfume. The growth is robust and the flowering free. The colour is deep orange-yellow, heavily veined and flushed with deep reddish copper. It is a splendid addition and flowers well in late autumn.

General McArthur is a variety with very strong perfume. Its colour is scarlet-crimson and is finest when the weather is not hot, for strong sunshine causes the petals to lose some of their brightness. The growth is free and the variety is always in flower; it is one of the best of autumn Roses.

Emma Wright is a variety of great beauty. The growth is clean and free. The flowers are a deep orange colour, not over large, but liberally produced. It deserves to be better known.

Madame Abel Chatenay is too well known to need description; it is still worthy of a place in any collection of Roses.

Mrs. Henry Morse is a fine Rose with pink or bright rose colouring, and it is sweetly scented. This variety is splendid for massing, being free flowering and producing blooms of large proportions.

Madame Edouard Herriot is coral red, shaded with rosy-scarlet. The season of blooming is early and late, and the plant is a splendid garden variety. The foliage and spines are attractive.

The Queen Alexandra Rose is of a unique colour—intense vermilion deeply shaded on the outer petals with old gold. This Rose should be planted alone to enhance its colouration. The foliage and growth are quite distinct and on a "Rose" soil would carry large and full blooms. The only white Rose I consider adaptable for bedding is the hardy Tea variety Mrs. Herbert Stevens. This sort has the making of a good bedding Rose, is free blooming, and excellent for general garden cultivation. The white is faintly shaded with Peach-pink towards the centre. *G. L.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

MR. KINGDON WARD'S SEVENTH EXPEDITION IN ASIA.*

No. 22.—THE GORGE OF THE TARON.

FROM an altitude of 3,000 feet the Taron looked a miserable ditch; but two things —noise and foam—told us it was in reality a formidable river.

An infamous descent down the backbone of a spur, carpeted with short, dry grass, tried my boots and my temper equally. Both gave way. On one side of us was a gully filled with mixed forest, in which Rhododendron sino-grande was conspicuous. This ceased on the spine, and the reverse slope, which faced the sun, presented the usual open park of Pine trees and Alders, growing in a deep sea of Bracken.

We did not descend quite to the river, but halted at the first cabin for lunch, and then proceeded by an execrable path down stream, keeping some hundreds of feet above the river. Bad as the path was, however, and slow as was our progress, it was nevertheless much better than I had dared to hope. The flank of the mountain was deeply fluted, and we had to climb up and down over endless spurs. The alignment of the path might have been more skilful, but we should have had to cross these spurs in any case. The vegetation was a wilderness of Bramble, Clematis, and many small shrubs; Luculia sp., being in flower, stood out by itself. Crawfurdia sp. and a large, lank Senecio of indolent habit were also conspicuous. The gullies were thickly wooded, and a species of Impatiens was in flower.

Eventually we reached a village of half a dozen log cabins, widely scattered on a sloping alluvial shelf; but owing to an epidemic, they were all deserted. However, we spent the night here, and next morning two naked savages came along and offered to guide us.

Before us was the torrent we had been compelled to abandon the previous day, flowing in a deep trench. It took us most of the morning to cross this, the path being almost vertical, so that we held on to roots and trees to let ourselves down. Progress was at the rate of under one mile an hour. In the forest above I found two species of Rhododendron, both moderate-sized trees; one of them at any rate was an Irroratum (K.W. 5445).

Only from the edge of the forest could one recognise the various trees; from the interior one saw only trunks draped with moss, and undergrowth.

In the afternoon we began to descend to the Taron by a spur even steeper than the previous one, and so slippery that it was almost impossible to keep one's feet, the soles of my boots being by this time highly polished. At last we reached the edge of the cliff, and had to proceed with more caution. A Rhododendron of the Virgatum series grew here in profusion, forming low, spreading bushes amongst the chunks of rock (K.W. 5446). Our descent ended in a forty-foot precipice, which we negotiated by means of a natural cable, to find ourselves on a sand bank in the bed of the Taron. A big tributary from the Salween divide roared in here.

On the cliffs were Pine trees, as well as large and fantastic-leafed Araliads; Orchids, as well as Rhododendrons. It was indeed surprising to find so many species of Rhododendron right down by the river, where the vegetation as a whole was distinctly semi-tropical. Here grew R. bullatum, and R. sino-Nuttallii, with other species of the Maddeni series. As I am probably the only white man who has seen R. sino-Nuttallii in nature, a short description may be interesting. It grew in deep shade, in the belt of jungle which clothed the tilted slate rocks in the river bed—a slim tree, fifteen feet high with a clean trunk. The truss is three or four flowered, and judging from the size of the capsules, which are three inches long, and an inch round at the base, tapering slightly, the flowers must be of very large size. The withered style is three and a half inches long. The leaves are larger than those of R. Nuttallii, but otherwise very similar, with the same lovely bronzed under-surface. The chocolate-coloured seeds have a peculiar unctuous texture, like soap-stone. The plant is, I imagine rare, and scattered, only three specimens being met with.

If the flowers are a good colour (as they certainly are not in R. Nuttallii), this species might prove to be the most sensational Rhododendron of its year, though I must confess that so far I see no very convincing reason to separate it from R. Nuttallii.

I collected much seed of it under the number K.W. 5466, and distributed it widely. What are the chances it will prove hardy?

The altitude of the Taron gorge (see Fig 86) here is about 6,000 feet—a fact about as useful as that it is situated in longitude 98° E. Owing to the high ranges which enclose the gorge, and the low snow line, it is very cold in January and February; it is also very hot in July and August, and always it is moist. Snow sometimes falls here, but does not lie for any length of time. Our winter would hold no terrors for R. sino-Nuttallii, but our August drought would certainly undo it. Given the shelter of a wood, and a moist soil, with adequate watering for eight months in the year, it would, I think, survive average samples of our climate, though we could easily hand out specimens which would tease it. On the other hand, the Maddeni series, like most of the Irroratums, Stamineums, Arboreums, and others, are tainted with a sort of Indo-Malayan poison, which is certainly going to make the Irrawaddy Rhododendrons touchy, until we discover exactly where the rub lies. Personally I would try R. sino-Nuttallii in North Wales, the Lake District, and West Central Scotland. Rainfall is more important than temperature—though no doubt there is a critical temperature for each species. It is not January and July isotherms, but radiation and stagnant cold air, which kill the plants. The home experts will doubtless plump for Cornwall; but I can see no sovereign virtue in a tempered climate with a forty-inch rainfall for a plant which comes from a region with a regular seventy-degree range of temperature and a hundred and twenty-inch rainfall.

The Taron is the Irrawaddy. We had taken six days from the Salween to the Irrawaddy, though a native with a 30-lb. load on his back would do the journey in three, so near to one another are they. When I found the forest so full of Rhododendrons the temptation to march north up the gorge was great; nor would it have been very difficult, as there are paths on both sides, and there is a regular trade passing up and down. In three or four days I could have been in the temperate forests. But I had set myself the task of crossing all the headwaters of the great river of Burma, and though it was obvious that Rhododendrons would become fewer and fewer as we went westwards, it seemed best to carry out the original plan. I could explore the Taron at some future date.

Crossing the river by "monkey" bridge, we marched several miles down stream, and camped on a sand bank. Here we rested a day—October 28—and I botanised. The trees, though varied, were mostly of small size. I noticed species of Ficus, Alder and Oak, most of them covered with epiphytic Orchids or shrubs, or muffled with creepers; here were masses of Ivy in flower, Agapetes, Aeschynanthus, Clematis, Akebia, and other plants. On the wet, shady cliffs, a yellow Chirita was abundant, and there were mounds of pink Luculia.

In one place the boulders just above high water were covered with the bulbs and foliage of a Crinum. (I brought home half a dozen bulbs in sand.) There was plenty of Bamboo; and where there was no forest, the slopes were covered with grass and giant herbs—Thistles fifteen feet high being especially prominent. Many queer Orchids were just coming into flower.

It was comfortably warm down here, the minimum temperature reaching 47° the first night, and only 52° the second night. Several fireflies added to the tropical appearance of the gorge. One felt in an entirely new world surrounded by vegetation in its strangest forms.

On October 29 we continued our march, and almost immediately turned west to cross the next range, sleeping that night several hundred feet above the river. *F. Kingdon Ward.*

PLANTS NEW OR NOTEWORTHY.

ILEX GENICULATA.

In September one of the prettiest-berried shrubs in the Arnold Arboretum is Ilex geniculata. For six weeks past it had been a plant of exquisite beauty, and will remain so, far into the winter, though shortly its leaves will fall. It is related to the common Black Alder (Ilex verticillata), and the plants agree in having deciduous leaves and male and female flowers on different individuals. In the American plant the fruit is very short-stalked and clustered in the leaf-axils, whereas in the Japanese species (Fig. 87), the fruits are suspended on slender, thread-like, purple-brown stalks, each from 1 to 2 inches long, with a curious little joint suggestive of a knee in the middle, from whence its specific name is obtained.

FIG. 87.—ILEX GENICULATA; A RARE SPECIES FROM CENTRAL JAPAN.

This Japanese Holly is a bush from 5 to 8 feet tall, symmetrical in outline, with many thin, ascending-spreading stems clothed with smooth, greenish-purple bark, and has thin, dull green, ovate to elliptic, sharply pointed leaves which are toothed along the margin. The berries are globose and about ¼ inch in diameter, lustrous, cinnabar-red, crowned with a black spot, and forcibly suggest beads of sealing-wax.

The plant grows wild on the mountains of central Japan, but is everywhere rare. I well remember happening upon the first wild bush of this Holly I had ever seen. It was on the scrub-clad slopes of Yatsuga-dake, when I was in quest of the rare Picea Koyamai, and quite accidental. The bush was about 6 feet high and as much in diameter, bearing thousands of its brilliantly coloured fruits suspended from slender stalks, and I thought I had never seen, in fruit, a shrub so lovely.

Ilex geniculata has been growing in the Arnold Arboretum since 1894, when plants were first received from the Imperial Forestry Department of Tokyo. In 1905 seeds were collected in Japan by Mr. J. G. Jack, of the Arboretum staff, and in 1914 by myself. The original plants and those raised from the two consignments of seeds have proved quite hardy in the Arnold Arboretum, and each year the female plants fruit freely. This species would appear to be very scarce, if not actually unknown, in Europe, for it is not mentioned in the Kew *Hand List*, nor in Mr. W. J. Bean's book on *Trees and Shrubs Hardy in the British Isles*. *E. H. Wilson, Arnold Arboretum, Harvard University.*

NOTES FROM WISLEY.

The autumn is the best time in which to consider the relative merits of those Barberries whose unassuming flowers develop into fruits of great beauty, while their hitherto inconspicuous foliage blazes into brilliance. In the latter category are the common Berberis Thunbergii, B. Jamesiana, with its red and gold tinted leaves, and B. yunnanensis, with its blood red foliage. The greatest charm, however, lies in the fruit. Some of the finest effects in this respect are seen in the B. Wilsonae hybrids, which are not only remarkable for the quantity of berries produced, but also for their exquisite colouring.

Considerable success has attended the raising of these hybrids at Wisley, and numbers are now to be seen in fruit in those gardens. The largest collection is planted by the side of the pond in the new field garden, and includes several kinds which have gained awards, such as the variety B. Autumn Beauty (see Fig. 77), which was exhibited at the recent Holland Park Show. Here also is B. Sparkler, with a regular rosette of leaves around the stalk of each fruit cluster, and the large-berried B. rubrostilla.

Among those which have not yet been shown is a variety with small but very numerous, translucent, pink fruits, tightly clustered round the arching shoots; another has berries of an almost orange hue.

In addition to variations in colour there is considerable diversity in the size and shape of the fruits. Some are spherical, others oval, and sometimes with pointed extremities, while others are conical in shape. The habit of growth varies also in different seedlings, as does the arrangement of the foliage. In order to perpetuate any one variety the most satisfactory method of propagation is that of layering.

An interesting Berberis in this portion of the gardens is B. pruinosa. This plant is evergreen, and bears, apparently, white berries. This white colour, however, is caused by a very heavy white meal, which, when rubbed off, discloses a greenish-yellow skin ripening to brownish red. The interior of the fruit is filled with the yellow juice common to Barberries. Another species of Berberis with berries carrying a white bloom is B. dictophylla. In this case the stems and undersides of the leaves also are white, after the manner of Rubus biflorus, and the fruits scarlet beneath the bloom.

In the border containing these Barberries is to be found Ligustrum ionandrum, which has for the first time at Wisley produced an appreciable crop of fruit. The berries are of a dull violet hue, and considerably enhance the value of this shrub as a garden plant.

In addition to Berberis, the banks of the pond have been planted with dwarf shrubs, such as Potentilla fruticosa (Farrer's variety) now blooming, and with some recently introduced prostrate Cotoneasters. Of the latter one of the best is C. rubens (Forrest). Some new Hypericums are growing up, a most attractive species being H. uralum (Forrest). This is cut down by frost in the winter at Wisley, but in the spring throws up graceful, Fern-like shoots from the tips of which yellow, bell-like blossoms appear in September

One of the finest of all the St. John's Worts, and most showy when in flower, is Hypericum

Digitized by Google

patulum Forrestii, which is now displaying its brown seed capsules and colouring its foliage. Our native Tutsan (H. Androsaemum), once famous as a medicinal herb, is also fruiting, the fruits taking the form of glossy, black, berry-like capsules. The leaves are remarkable for the resinous smell emitted when bruised.

The shrubs in flower at the gardens at the present time are but few. Among them are Clerodendron trichotomum, with its fragrant, waxy blossoms contained within a pink calyx, and the pink flowered Abelia grandiflora. Buddleia Farreri is unfortunate in that it does not get an opportunity of flowering in the open owing to its susceptibility to frost. It is noteworthy for the very dense white tomentum which covers the stems and young growth, and for its winged petioles.

On the rock garden Gentiana Farreri is in flower, and the blooms of a number of Cyclamen neapolitanum and its white variety are springing up. *J. E. G. White.*

EDINBURGH BOTANIC GARDEN NOTES.

Of the numerous Hypericums flowering in the garden H. patulum Henryi is the most attractive. The large flowers with tufts of conspicuous stamens are borne in clusters at the tip of every growth. Spartium junceum on a slope in the arboretum is a wealth of colour, the environing shrubs providing the background necessary to display to advantage the leafless, whip-like branches crowded with yellow bloom. Elsholtzia Stauntonii, a dwarf shrub flowering in the border by the terrace wall, might be mistaken at first glance for a Veronica; the small carmine flowers are in terminal spikes, and the foliage, when bruised, is aromatic. On a ledge in the rock-garden Abelia Engleriana is flowering; the tubular flowers are deep pink in colour.

Primula pseudo-capitata, P. capitata, P.-c. viridifolia, and P.c. Mooreana are among the best of the late flowering Primulas, P.-c. Mooreana, with Tyrian violet flowers, and powdered stems, being especially fine. Gentiana sino-ornata, bordering one of the paths in the rock-garden, is a sheet of vivid blue. Here also is Gentiana Farreri—"special pilgrimages go to Edinburgh to see the jungles of Gentiana Farreri, a yard through with some 300 gigantic trumpets opening at once." More subdued in their colouring are the many square yards of the prostrate growing Pratia angulata and P. arenaria covered with delicate white Lobelia-like flowers.

A study in contrasts is afforded by a group of Yucca filamentosa antwerpensis, with several stately inflorescences, in close proximity to Convolvulus mauritanicus, whose trailing growths are wreathed with light blue flowers. Other subjects flowering in the rock-garden include Dracocephalum Forrestii, a bright, blue-flowering Labiate, and an extensive drift of Astilbe simplicifolia, with bronze-tinted foliage and graceful panicles of white flowers, 9 inches high.

Three good Asters in the herbaceous border are the large flowering Purple Emperor, Perry's White, and Anita Ballard, Cornflower blue, Erigeron speciosus superbus is flowering freely, and the colour, rich mauve, is very effective in the mass. Anemone elegantissima is a handsome japonica variety, vigorous growing, with large, semi-double pink flowers.

Mustisia ilicifolia, a scrambling shrub, covered with a cobweb-like tomentum and Daisy-like flowers 3 inches across, pink and white, is flowering on the roof in the alpine house. Other plants on the indoor rockery are Fuchsia parviflora, laden with glossy, black, globose berries, the size of Peas; the flowers are small and insignificant. Cowania plicata, a dwarf shrub, with Rose-like, single, dark red flowers; Dendromecon rigidus, the Californian Yellow Tree Poppy; Isoloma senequioides; Amphicome arguta; Alströmeria (syn. Ligtu) Hookeri; and the fragrant Heliotropium anchusaefolium.

On the wall in the corridor the large white, trumpet-shaped flowers of Datura cornigera are conspicuous, as are the many-flowered clusters of Bomarea Caldasiana, orange, heavily spotted with crimson. The clear yellow Abutilon, Golden Fleece, and the free flowering violet-coloured, climbing Maurandia scandens, and the M. semperflorens are also notable.

A batch of Spathoglottis edinensis is in bloom in the warm Orchid house, with other showy species and hybrids, Cattleya Atalanta, C. Ella × Dowiana, Laelio-Cattleya Dominiana, L.-C. callistoglossa, L.-C. Nysa, L.-C. Nysa superba, Coelogyne Cummingii, C. lagenaria, and hybrid Paphiopediums. Suspended from the roof are baskets of Columnea gloriosa superba, with small green foliage and large bright scarlet flowers *Fred W. Jeffrey.*

FLORAL DECORATIONS.

The art of floral decorating has suffered a great deal during the past few years, for whereas many country establishments employed "a man well up in decorating," now, for the most part, the large houses are sparsely adorned with flowers, while groups of plants are seldom used.

It appears to me that the only way for a keen, young gardener to obtain experience in the art of floral decoration is to seek service for a while with a good firm of florists, who specialise in decorating for weddings, balls, and other functions. If he has a few years of practical gardening experience behind him, the break of a year or so in studying this art should do him no harm. Of course, it is not always easy to get into the employ of really good firms, still, there are possibilities. The gardening world is gradually coming into its own again, and, no doubt, floral decorating will presently play an important part once more. It is with that hope these notes are written.

The decoration of the dinner-table used to be a very important part of the work of the decorator. In such work there are several points to be considered in securing a pleasing effect. The vases should be suitable in size and shape; large vases will produce a heavy effect, and very small ones will suggest meanness. Care should be taken not to obstruct the view across the table, therefore the flowers must not be more than 16 inches above the table, or, if very tall vases are used, there must be nothing in them to hang lower than 24 inches from the table. As a rule, a dinner-table decoration will consist of a principal or centre decoration and a few subordinate or smaller ones. If there is to be a dinner party of, say, twenty-four or more people, two or three equally important decorations, varying in accordance with the length of the table are required, and a corresponding number of smaller ones. In these cases Palms and Dracaenas may often be used to good effect as the central features.

When flowers of different hues are used care must be taken that the colours do not clash. Some colours will not associate kindly, and there is nothing worse than to see a vase of mixed flowers in which the colours are crudely arranged. Lightness of arrangement is a great point in floral decorating. Some flowers, especially Roses, have a tendency to look heavy when put into a vase, and this should be guarded against. It is always well to remember that dark flowers need a light position, in front of a window or doorway, and flowers of a light colour should be put into the darkest situations. The use of Smilax and Asparagus around long stems, and the addition of suitable foliage must be left to the discretion of the decorator.

To arrange a group of plants so as to promote an artistic and pleasing effect is not an easy matter, especially when several kinds of plants are to be used. Hydrangeas, Rhododendrons in pots, Rambler Roses in pots, and Chrysanthemums are a few subjects that always form pleasing groups when well arranged. When foliage plants, such as Ferns, Crotons, Coleus, etc., are used in making groups, care must be taken that they assist the flowering plants, and do not dominate them; many groups are spoiled owing to lack of consideration of this matter.

Button-holes and bouquets both come under the heading of floral decorations; but domestic decorating is the more important from the gardener's point of view. *H. W. Stenning, Ebrington Hall Gardens, Gloucester.*

PELARGONIUM ROLLISON'S UNIQUE AND OTHERS.

Your correspondent *T* in the issue of September 29 (p. 191) rather tickles my sense of humour in the tacit way he seems to suggest an "appeal to the umpire." We do know a little about Scented Pelargoniums at Aldenham, but I certainly do not lay claim to expert knowledge. I have not observed that any of our plants of Rollison's Unique vary in the colour of flower at any period, nor any of the other Uniques, of which we grow Aurora Unique (the best of all), Purple Unique, Scarlet Unique, Shelton Unique and White Unique, in addition to Rollison's. I am not suggesting for a moment that Mr. Lynch has not done so, for I rather fancy that something of this colour change takes place in Pelargonium echinatum var. Ariel, as it seems to lose its pale pink tone at times and then closely resembles P. echinatum—to our confusion, be it confessed. Probably there is some well-defined law controlling the question of colouring in flowers and foliage, for we have shrubs that at times, after freely exhibiting their variegation, revert to green, owing to restoration of chlorophyll, only to relapse again after a season, and this trick seems to occur more or less regularly at intervals with certain plants.

Mr. Coomber makes a rather strong suggestion, inasmuch as whilst, no doubt, enthusiasts in these matters would delight to carry over groups of plants during periods of depression, until such time as they regained favour, even gardens like Aldenham could hardly undertake such a task, for it would be an enormous enterprise. Is not this work rather more fitted to the functions of National Botanic Gardens such as Kew?

Aldenham already has about 120 different Cape Pelargoniums (all grown in pots, by the way, and none wall trained), as the Hon. Vicary Gibbs takes a very keen interest in this group. But even that number is comparatively small considering the fact that during the period of 290 odd years since the first species arrived in this country, nearly as many (about 270) species of the various groups have been recorded of the Pelargonium family, besides innumerable varieties and forms, and one wonders where some of them have gone to.

Whilst dealing with this subject I would urge the claims of Cape Pelargoniums as being both interesting and beautiful alike for the greenhouse, for house decoration, and for summer bedding, as they require only sufficient heat whilst under glass to maintain the temperature comfortably clear of frost. They ask for little attention during their period of growth, other than watering and shaping.

For bedding purposes these Cape Pelargoniums are ideal and the plants may readily be grown in either bush, pyramid, or standard form, the latter making ideal plants up to 5 ft. and 6 ft. tall, thus lending very suitable relief to otherwise low-level bedding. Their very variable characteristics of growth, habit, foliage, and colour and appearance of flower add to their charm, and at Aldenham we employ them largely with great advantage.

Cape Pelargoniums have been in the background for a long period now, but are unquestionably coming into favour again, and many folk are seeking them, realising their beauty and utility. A few of the best species and varieties are as follow:—Rollison's and the other Uniques mentioned above; Moore's Victory (Syn. P. Mooreanum); Mdme. Nonin, P. Blandfordianum, Lady Plymouth, Shottesham Pet, Pheasant's Foot, Mrs. Kingsley, P. pinnatum, P. artemisifolium, P. tomentosum, Prince of Orange and its variegated form; P. ardens, P. Zermattii, P. echinatum, P. echinatum var. Ariel, P. Schottii, P. crispum variegatum, Princess of Orange, Dale Park Beauty, Clorinda, Lady Scarborough, Stag's Horn, P. tricolor, Shrubland Pet, Pretty Polly, P. cuculatum flore-pleno, P. rapaceum, Mrs. Kingsley, Shrubland Rose, Attar of Roses, and P. odorum roseum. *E. Beckett, Aldenham Gardens, Elstree, Hertfordshire.*

THE BULB GARDEN.

DARWIN TULIPS.

The popularity of the Darwin Tulip has increased enormously of late, and right well does the flower deserve the favour of the gardening public, as it possesses so many good qualities. A wide range of colour, a vigorous habit of growth, and the wonderful lasting quality of its flowers are some of its chief virtues. Then the long flower stem in this strain of Tulip makes it very valuable for cutting, and again as it flowers in May, when the weather has usually lost some of the bitter sting of our average English spring, its beauties can be better enjoyed than is the case with flowers opening earlier in the year.

I will first give a list of what I consider the very best and most distinct varieties, and then a few cultural hints.

Red Varieties.

Bartigon: Rich deep red, a very sturdy grower in the open and a good forcer, but has one weak point; it often has one or more greenish petals; height, 22 inches.

Claude Gillot: Large, crimson-scarlet flower, a beautiful glowing colour, very much like Glow, but a little superior; 26 inches.

Europe: Vivid Cherry-red, clear white base, rather near to Farncombe Sanders, but a little brighter and opens out a little more fully; 26 inches.

Farncombe Sanders: An immense, bold flower of a bright Cherry-red; the flower lasts wonderfully well. If I grew only one Darwin Tulip it would be Farncombe Sanders; 28 inches.

Feu Brilliant: A very fine deep scarlet, very like Isis, but a shade deeper in colour; very fine; 29 inches.

Harry Veitch: Deep blood-red, a large and well-formed flower; 23 inches.

Henner: Deep blood-red, inclining to maroon, a fine bold flower; 26 inches.

Orion: Large flower, brilliant dark scarlet, with blue base.

Prince of the Netherlands: Glowing Cherry-red, flushed with a deeper shade of red. One of the largest sorts in cultivation; a very strong grower; 28 inches.

Professor Rawenhoff: Almost too much like Farncombe Sanders; good for forcing.

Salmon King: The blooms are rich deep glowing salmon when young, but Cherry-red when fully developed; a very pretty bright flower, but rather small; 25 inches.

Eclipse (New): A very fine variety; the flowers are of large size, well formed and of a rich blood-red colour; 25 inches.

Rose Varieties.

Edmée: Vivid rose, edged pale pink, a well-formed flower which lasts a long time. There are at least six Darwins in the same style of colouring, as Mme. Krelage and Baron de la Tonnaye, but I consider Edmée the best of the set; 27 inches.

Loveliness: Bright satiny rose, lighter margins to the petals; a very lovely flower when well grown, but it is not a very robust grower; 22 inches.

Nauticus: Very deep rose, base dark violet; a large, showy flower and distinct; a very robust grower; 24 inches.

Petrus Hondius: Deep rich rose, large flower and quite distinct. This variety was not much thought of until the last year or two, but now it is much sought after; 24 inches.

Pride of Haarlem: Not a pure rose, but I do not know of another colour heading more suitable for it. Flowers of largest size and good form; one of the very best and most showy varieties; very early; 26 inches.

Maroon Shades.

Andrea Doria: Deep rich maroon, large, well-formed flower, very good constitution; one of the best of this class of colour; early; 33 inches.

Leonardo da Vinci: Dark purple-maroon, strong grower; flowers large; 23 inches.

Faust: Dark satiny purple, with blue base; very large and well-formed flower; good forcer.

La Tulipe Noire: This deserves a place to itself as the colour is deeper than maroon, and is as nearly black as any Tulip is likely to be. A large flower with a peculiar satiny sheen; 24 inches. There are numbers of these blackamoors, but one or two of the best are sufficient for any but the largest collections.

Pink Shades.

Clara Butt: Pale rose-pink, a most distinct and lovely Tulip, probably the most popular of all the Darwins; rather late; 22 inches.

Julie Virnot (Princess Elizabeth): Vivid rosy pink, edge of petal lighter. The young bloom is like Clara Butt, of a deeper shade of pink. Very beautiful and a good forcer; 25 inches.

L'Ingénue: White, delicately suffused with rose; a very attractive flower and one that lasts well; 29 inches.

Margaret: An egg-shaped flower, outside blush, inside delicate rose. The flower reminds one a little of very delicate egg-shell china; late; 20 inches. Good for pots.

Suzon: Soft rose, blush white at edge of petal, centre, Cambridge blue. A large flower and very attractive; 28 inches.

Mauve Shades.

Bleu Aimable: Deep mauve, a very distinct shade; has been very scarce of late, but is now fairly plentiful; 23 inches.

Erguste: Bright silvery mauve, rather long pointed bloom; a pretty variety, but rather prone to "fire"; 27 inches.

Euterpe: A good mauve, with a slight tint of lilac; a good, lasting flower; 27 inches.

Pensée Amère: Purplish lilac, very beautiful, good forcer.

Rev. H. Ewbank: A beautiful silvery mauve, one of the very best in this class of colour; good sturdy grower; 20 inches.

Purple Shades.

Frans Hals: A very handsome flower of immense size and coloured rich violet-purple; perhaps the finest purple Darwin; 30 inches.

Marconi: Deep rich purple, white base, huge well-formed flower of cup form, very strong grower; a remarkably fine variety; 30 inches.

Mrs. Potter Palmer (Fashion, D. T. Fish): Bright purplish violet, fine large flower, distinct and beautiful; late.

Ronald Gunn: Flowers very large, purple-plum colour, edges of petals silvery white; a noble flower and quite distinct; 25 inches.

The Bishop: A long flower of very striking colouring; a rich purple, shot with lilac; plant very vigorous, very late; 29 inches.

Valentine: An early variety and very beautiful; flower large, bright violet with electric blue centre; 30 inches. *J. Duncan Pearson, Lowdham.*

(*To be continued.*)

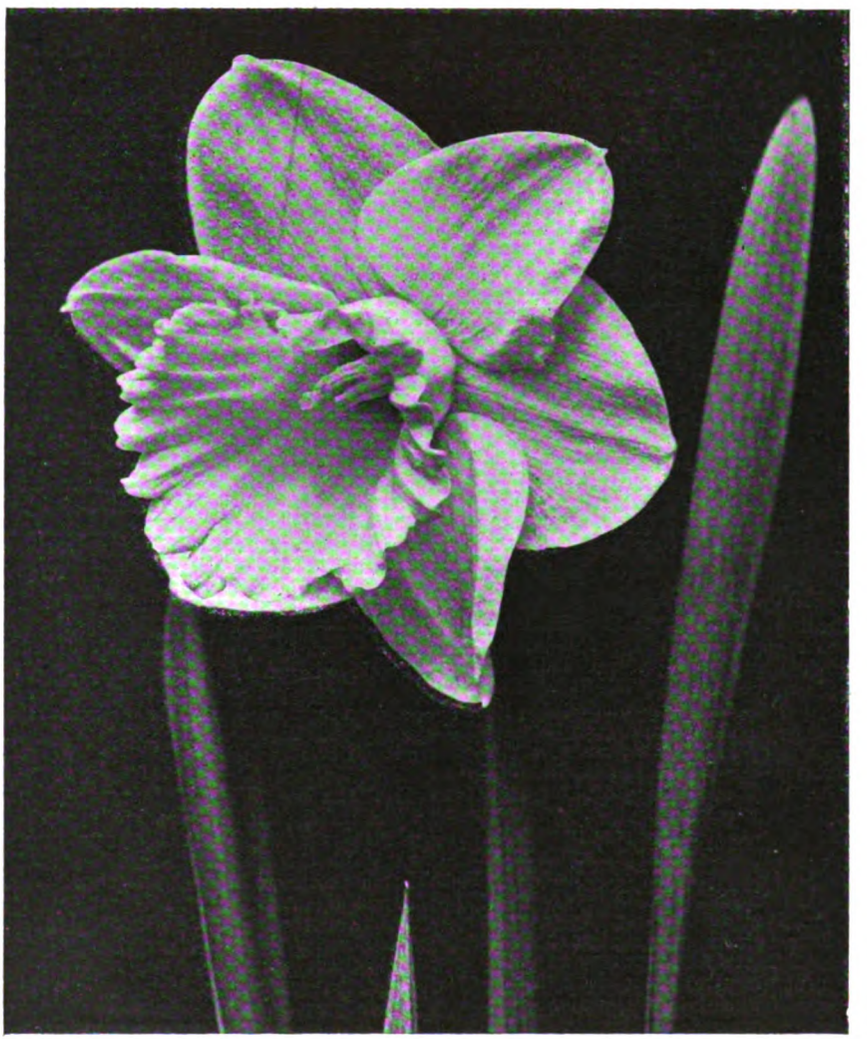

FIG. 88.—NARCISSUS NERO.

NARCISSUS NERO.

The fine new Daffodil illustrated in Fig. 88, named Nero, is a very large yellow Ajax of the Cleopatra type. The perianth is rounded and of great width, the major segments meeting at the back of the flower. As will be seen on reference to the picture, the trumpet is expanded and well frilled at the edge. Dr. N. Y. Lower, of St. David's, Presteign, who has shown this beautiful Daffodil on several occasions, informs us that the variety is a good doer and a very free bloomer; also that the colour is a uniform clear yellow.

DEVELOPMENT OF THE DAHLIA.*

(*Continued from page* 221.)

From France came Agnès Lord, Beauté de Paris, Champs Elysées, Charivari, Duchesse de Nemours, Gloire de Douai, Triomphe, Rouillard, Marèchal Pelissier, Général MacMahon, Vierge Marie, Biribi, Madame Chauvière.

The most noted Belgian varieties were Fleur de Gand and Souvenir de Gand, P. P. Rubens, Pierre de Bex, Koning der Belges, Nieuwe Glorie, Madame de Man de Lennuck, etc.

About 1855 the large, ball-shaped Show Dahlia, of which I have spoken here almost exclusively, had reached such a standard of perfection that it could hardly be improved further, and many flowers offered for the first time in that period have kept their position as commercial varieties during forty years.

Fashion had favoured the Dahlia for such an unusually long period that it is not to be wondered at that a certain decline set in. In his catalogues of 1847-8 my grandfather remarks that novelties are being offered yearly which do not surpass the older ones and heavily disappoint the amateurs. He therefore does not offer any of the newest Dahlias (of which in 1846 alone 300 were offered at an average price of 10s.), and only lists an assortment of 200 selected varieties.

It is evident that the opportunities for deception and disappointment, as referred to in this notice, were not good stimulants to the purchase of Dahlias. In 1864 any firm's special Dahlia list, in an introductory remark, states that "the glorious days for the Dahlia have passed, and that indifference has replaced the amateur's interest."

And so it was not only in Holland, but all over the world. The large Show flowers still remained the chief group, but not until the rise of the Cactus Dahlia did fashion again bestow her high favour on this genus of plants.

The Lilliput Dahlias.

Before dealing with the Cactus Dahlia, we have first to record the raising of a group of flowers which made its appearance in 1851 under the name of Lilliput Dahlias. They were obtained from seed by Sieckmann, and distinguished by small globular flower heads. The first notice of this new class was given by Sieckmann in the *Thüringer Gartenzeitung* of August 31, 1850, and two years later they were figured on a coloured plate in Regel's *Gartenflora*. In the accompanying article Sieckmann tells that he had grown them for six to eight years.

The Lilliput Dahlias, which were later also known as Pompon Dahlias, have quite recently become more appreciated than in any former period. Their free-flowering properties and their neat, small flowers lend them a decided charm for certain decorative effects in the garden. In our days they are the only form of the old-fashioned ball-shaped Dahlias which are still tolerated in our gardens.

The Green Dahlia.

It was again Sieckmann who in 1873 offered the green Dahlia in his catalogue. He made a great fuss about it, wholly out of proportion to the object of his exaggerated advertisement. He called it "Gottes Wunder," and published a quaint poem of an admirer in his catalogue:

Single Dahlias.

Sieckmann seems to have been very fond of polemics. His catalogues are full of attacks upon and challenges to the raisers of other nationalities as soon as they introduce new types which he had not raised himself. So Sieckmann was a strong opposer to the single Dahlias which made their appearance in England about 1880, but he nevertheless listed and offered them in yearly increasing number in his catalogues.

The ball-shaped Dahlias had reigned so long without rival that every change in the general character of the flower was welcomed with enthusiasm. The wild growing Mexican Dahlias, whether still kept in their original form or reintroduced from their native country, were at last appreciated for their natural beauty and attractive elegance. They came to the front at shows, and in 1879 a single form Paragon, which gave the impression of a wild species, attracted general attention at a Royal Horticultural Society's meeting in London. The Dahlia growers soon took advantage of the public's preference for single flowers, and within a couple of years extensive assortments of single Dahlias were offered in the English catalogues, and, soon afterwards, also in Continental catalogues. Seedlings of this class were raised everywhere, and it would be difficult to decide from where the best came, although the English raisers kept more accurately to the officially fixed shape than others.

(*To be continued.*)

* A paper read by Mr. Ernest H. Krelage before the International Horticultural Congress at Amsterdam, on September 18.

PRUNING FRUIT TREES.

For some years past I have commenced the pruning of fruit-bearing subjects at this time of year, beginning with Currants and finishing with Apples—in advance of defoliation. At first the reason for such early pruning was the need for getting the work out of hand as soon as possible; but there are other recommendations.

One advantage is that the operator sees exactly how to thin out shoots to a nicety, and not only shoots, but also large congregations of spurs and the useless sprays that are formed among these, which, in Pears, are particularly noticeable, and of no use to the trees. Instead of pruning or cutting these off it is best to rub them off, by which means the development of more spray growth is effectually stopped.

Though probably not so hurtful as over-cropping, yet a long period of observation has convinced me that even a condition of over-foliation is opposite to beneficial to the production of blossom, and healthy blossom at that, for much of the blossom on overcrowded growths will, on examination, be found abnormal, wanting even in embryonic ovules. Moreover, where fruit sets, more especially in the case of Plums, it is notorious that most of it drops previous to the stoning period; but Apples also are apt to drop similarly. So certain are these effects that the condition of the future crop may be fairly well gauged by an examination of the flowers. Sometimes the anthers are abnormal, but the great cause of inefficiency rests in the female organs being immature or wanting. That is why an enormous flush of blossom is sometimes followed by a disappointing crop of fruit.

We do not want large displays of blossom, but what blossom there is should be perfect, and that, as one means, can only be secured by letting the greatest possible amount of light and air play upon the foliage, and these efficients can be obtained more perfectly by pruning before the leaf falls than subsequent to that state.

It also has the remarkable property of causing a stronger set of shoots than when pruning is deferred till spring. This, of course, in the case of over-vigorous trees may be distinctly prejudicial to fruit production, but in these circumstances root pruning is the proper thing to do, and as recently noted in an article on the subject, September is the best time for the work, and not, as some assume, while the trees are quiescent during winter.

Exactly the same treatment applies to Grape vines. As a means of keeping them in vigorous health they should be pruned at the yellowing of the leaves. Some cultivators cut back the laterals to half their length long before that stage, and I have done it myself, but I am not sure that it is an expedient that can be commended. But as to the value of early pruning, as compared with leaving it till winter, I am certain that whoever has tried it over a series of years must have noticed its advantage. I like to prune outdoor Figs in August, thinning finally in May. Probably it would be better to treat these like other fruit trees, but I have not tried it. *R. P. Brotherston.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Holland Park Hall Show.—I have not failed to attend the "British Fruit Show"—as we have always termed the special autumn fruit exhibition of the R.H.S.—for the past sixteen years, generally as an exhibitor, and in my opinion the late show was by far the worst I have seen during that period. This I attribute to more than one cause; the present season has been one of the worst known for hardy fruits over a period of many years, but there are other causes which ought not to exist. In the days when the exhibition was held in the Royal Horticultural Hall, Vincent Square, we not only had a fine show, but there was good fellowship and hearty co-operation between all concerned—the officials of the Royal Horticultural Society, trade growers, gardeners and amateurs. As our late, highly-respected friend, Mr. S. T. Wright, once said to me when he managed these gatherings, it was "the happiest show of the year, a real gathering of the clans, where men met in healthy, hearty competition and exhibited the finest fruits of the world." At such times everyone was considered and everything was done to make things easy for exhibitors; a feeling of comradeship existed everywhere, a grumble was scarcely ever heard, and we had a British fruit show worthy of the name. At the recent Holland Park Hall show the competitive fruit classes were not worth going to see, and the reason, in great part, was the autocratic way in which exhibitors and would-be exhibitors were treated by the officials of the Society. Take my own case—the schedule stated that all exhibitors must enter by August 30. After carefully wading through forty-three different rules, I sent my entries before that date, fifty-two in all, which I would have filled creditably. I received a letter, over a week after the closing date, saying evidently I had overlooked a new rule, which I found, quite apart from the other rules (consisting of a line-and-a-half of small type), practically changing the whole conditions of the show. This rule states that unless exhibitors entered in certain classes (in other years barred) they would be restricted to six dishes of dessert Apples, six dishes of cooking Apples, and nine dishes of Pears. I at once wrote stating that I was very sorry I had overlooked this new rule, and that I was away from home, but to simplify matters would they accept my entries in the extra classes mentioned, and so allow my original entry to stand. I received a very curt reply to the effect that I would be given two days to revise my list; that once a rule was made it could not be broken—hence my exhibits in those classes only. Many other would-be exhibitors informed me that they were treated in similar fashion, whilst others, among them some of the finest fruit growers in England, had all their entries returned with the information that these could not be accepted as August 30 had passed. Is it to be wondered at that large empty spaces were to be seen everywhere? Fortunately, exhibitors are not treated in this manner at provincial shows, for if all societies adopted this attitude there would quickly be no exhibitions. Again, why should the fruit and vegetable classes be relegated to the galleries, whilst all the floor space, with the exception of the trade exhibits of vegetables and fruit, is filled with flowers—and yet this is supposed to be the chief fruit and vegetable show of the year. There were no notices put up to inform the public such a show was held upstairs, and on the first day of the show in particular I doubt if more than five per cent. of the people who attended saw the competitive fruit and vegetable classes. The police arrangements, too, were very bad. Last year I lost many of the best dishes of my fruit, and there was not a whole dish left of all that I exhibited. This year the same thing commenced until I complained that fruit was being stolen, when the police were sent to the galleries and the thieving ceased. Unfortunately, too, the shows of the Royal Horticultural Society

Digitized by Google

are becoming the haunts of a thieving gang who not only steal fruits and flowers, but go through the pockets of unsuspecting exhibitors, and take money and other valuables. The authorities should warn exhibitors beforehand, and no stone should be left unturned to bring these criminals to book. It is not pleasant to be left stranded in London without a penny in one's pocket for four days. Many were, unfortunately, left in that position at the recent show, I among them, and I write this in the hope that it may be a warning to others. *Lewis Smith.*

—In your able criticism of the recent show held at Holland Park Hall, you suggest that the council of the R.H.S. had no alternative to the Rink as a venue for the exhibition. I suggest that a far superior building in many ways would be the New Annexe to Olympia. It is much larger than the Rink, possesses a wide gallery (with lifts), there is an abundance of light, both natural and artificial, plenty of room for unloading exhibits, and the floor is not likely to be spoiled if water happens to get spilled. There should be ample opportunity there for the granting of two very necessary items—a room for the press and free cloak-room for exhibitors and their assistants. The facilities for catering in the new hall are excellent. Perhaps the council of the Royal Horticultural Society might see its way to hold one of the spring bulb shows in this hall, as the crush at the spring shows in Vincent Square is becoming so great that it is impossible to study the exhibits in comfort, with consequent loss of business by traders. I think, too, that a four-day show in the spring, well advertised, and with a reasonable entrance fee, would attract many thousands of visitors. *Jas. S. Dakere, Forest Hill, London, S.E.*

Cydonia japonica Flowering on a Sucker Growth.—I am sending you a specimen of Cydonia japonica, which shows this plant flowering on a short sucker growth. It seems to me to be a very curious freak, especially as the white variety is not very free flowering and usually blooms only on well ripened wood. *R. Windsor Rickards.*

[The short sucker growth consisted of comparatively soft wood, and carried four fully developed flowers of the white variety of Cydonia japonica.—Eds.]

Pea The Gladstone.—I am sending you a sample of green Peas which I hope will interest you. They represent the variety The Gladstone, and are from plants we have been gathering from since August 25, and the Peas are still of good quality when cooked. The pods I send you were taken from quite near the top of the haulm, and I think you will agree that for this northern district the plants have cropped remarkably well over a long period. Quite recently the stems were attacked by leather jackets, which we effectually combatted by sprinkling "Tipulite" on the ground in the neighbourhood of the rows. *W. G. Holmes, Tain, Ross-shire.*

[The pods sent were of fine size and fairly well filled with good Peas of excellent colour and quality.—Eds.].

Cannon Hall Muscat Grapes.—Your readers will remember that in some notes on the Cannon Hall Grape I stated my son and I were experimenting with a system entirely different to that practised with other varieties in pruning, disbudding, stopping of laterals, watering and feeding, with a view to getting the berries to set more satisfactorily. How far we have succeeded readers may have seen at Holland Park show in the winning set of twelve bunches, which included two bunches of Cannon Hall, while in the class for two bunches of any white variety we also gained first prize. It is remarkable that this Grape has been condemned because of its bad setting quality. Our vines of this variety have been planted only four and a half years, and are likely to give a good account of themselves if they continue to receive the treatment needed. *W. Irvine, senr., Bradley Gardens, Grimsby.*

SOCIETIES.

ROYAL HORTICULTURAL.

October 6.—The Royal Horticultural Hall, Westminster, was well filled with exhibits on the above date, and visitors were fairly numerous for the time of year. Michaelmas Daisies were very much in evidence and Chrysanthemums added to the autumnal effect. The Hon. Vicary Gibbs contributed a splendid collection of berried shrubs and others with coloured foliage. Orchids were not largely shown, but Carnations, Scabious, Roses and fruits were well displayed.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Viscount Sohma of Japan, the Hon. H. D. McLaren, Messrs. Jas. O'Brien (hon. secretary), Gurney Wilson (assistant secretary), Arthur Dye, J. Wilson Potter, S. W. Flory, W. H. White, H. T. Pitt, J. E. Shill, C. H. Curtis, H. G. Alexander, Henry H. Smith, Richard G. Thwaites, Pantia Ralli, R. Brooman White and C. J. Lucas.

First-Class Certificates.

Cypripedium Albion, Bodnant variety. From Lady Aberconway, Bodnant, N. Wales (gr. Mr. F. C. Puddle), and the Hon. H. D. McLaren. This charming hybrid was raised by crossing C. niveum var. Goliath and C. Astarte (insigne Sanderae × Psyche). C. Psyche results from crossing C. bellatulum and C. niveum, and in the present charming cross the interesting feature is that while it is an improvement on other white Cypripediums, some faint traces of colour appear, while C. niveum, amplified, predominates. The small seedling bore a model flower of wax-like texture, snow-white with a few very faint dark dots on the petals.

Cattleya Mrs. Gratrix (*Lady Veitch* × *intertexta Juliettae*), from Messrs. Sanders, St. Albans. A model flower and one of the finest white Cattleyas. The sepals and very broad petals make up an almost perfect flower; the broad lip, which is circular in outline, is crimped at the edge and has a yellow disc.

Other Exhibits.

Messrs. Cowan and Co., Southgate, were awarded a Silver Banksian Medal for a select group, including Cypripedium Mario (Draco × Earl Tankerville), a finely formed flower with a well-rounded white dorsal sepal, emerald green at the base and spotted with red-brown; the fine white C. Boltonii, C. Leeanum Corona, C. Dreadnought, C. King George V., and other Cypripediums; Laelio-Cattleya Soulange, L.-C. luminosa aurea, Cowan's variety, certainly the best of this favourite cross; Cattleya Phoebe, C. Hardyana alba varieties and other Cattleyas.

Pantia Ralli, Esq., Ashtead Park, Surrey (gr. Mr. Farnes), sent a finely grown plant of Vanda luzonica, Ashtead Park variety, with a spike of fourteen wax-like white flowers with mauve lips and slight rose markings on the edges of the petals.

Messrs. Charlesworth and Co. Haywards Heath, showed a selection of fine hybrids, the best of which was Sophro-Laelio-Cattleya Prince Hirohito var. Vesuvius (S.-L.-C. Marathon × S.-L. Leda). The plant bore a fine spike of three flowers of rich red-mauve colour with ruby lip. A grand form of Cattleya Enid alba, a clear white Odontoglossum eximium virginale with sixteen flowers, the new Odontonia maculata (Miltonia Bleuana × Odontoglossum Harwoodii), a very pretty yellow-ground flower spotted with purple and with showy mauve lip, and the pretty Vuylstekeara Memoria Joseph Charlesworth were also shown.

Floral Committee.

Present: Messrs. H. B. May (in the chair), D. B. Crane, G. W. Leak, Amos Perry, A. G. Jackman, W. P. Thomson, W. B. Gingell, W. Howe, C. R. Fielder, E. A. Bowles, W. J. Bean, H. J. Jones, John Heal, M. C. Allwood, Donald Allan, J. Jennings, J. F. McLeod, Sydney Morris, H. V. Warrender, W. B. Cranfield, J. B. Riding, R. C. Notcutt, H. D. McLaren, Reginald Cory, H. R. Darlington, Gerald Loder, W. G. Baker, Chas. E. Pearson and Sir Wm. Lawrence.

The Floral Committee was called upon to consider the merits of twenty-eight plants and flowers and thirty-nine groups.

Awards of Merit.

Aster October Dawn.—A large-flowered variety of clear soft blue colouring. The florets are pleasingly and gracefully arranged, consequently the flower heads present none of the stiffness so often associated with large-flowered Asters. Shown by Mr. E. Ballard.

Aster Aldenham Pink.—A neatly flowered variety with blooms of a rich bluish rose colour, rather different to the colour usually described as pink. Shown by the Hon. Vicary Gibbs.

Chrysanthemum Elsie.—A large-flowered Japanese variety, with broad florets of rich yellow colour. A promising variety for exhibition purposes. Shown by Mr. G. Carpenter West Hall Gardens, Byfleet.

Chrysanthemum Godfrey's Gem.—This is a single variety—at least, it has three rows of florets and thus comes within the N.C.S. definition. The flowers are of medium size and a brilliant orange-buff colour that is very attractive. Shown by Messrs. Godfrey and Son.

Berberis brachypoda Gibbsii.—A very fine Barberry and of distinct habit. The growth is erect and carries formidable spines and stout oblanceolate leaves. The light coral red berries are borne in depending clusters and are freely produced. A very showy shrub. Shown by the Hon. Vicary Gibbs, Aldenham House, Elstree.

Pyrus Aucuparia munda subarachnoideum.—An interesting form of the Mountain Ash bearing clusters of white berries. Shown by the Hon. Vicary Gibbs.

Berberis Tom Thumb.—This should prove an interesting and useful plant for the rock garden, as it is of dwarf, dense habit, attaining barely one foot in height. The parents are B. aggregata and B. Wilsonae, and the influence of both those species is evident in the progeny, but how the stunted growth arises is not so evident. The berries are coral-red, much like those of B. Wilsonae, but not so freely produced, nor is the plant so graceful. Shown by Mr. Sydney Morris, Earlham Hall, Norwich.

Scolopendrium vulgare ramo-crispissimum conglomeratum.—A dense-habited variety of the old Hart's Tongue Fern. The fronds are short, broadened, crisped and crested. Shown by Mr. Amos Perry.

Scolopendrium vulgare muricatum fimbriatum capitatum.—In this variety the long fronds are so crisped that the folds of the frondage overlap. There is also a tasselled crest. Shown by Mr. Amos Perry.

Groups.

The most important exhibit in the hall, both as regards size and general attraction, was the large collection of specimens of hardy trees and shrubs displayed by the Hon. Vicary Gibbs (gr. Mr. E. Beckett, V.M.H.), Aldenham House, Elstree. Naturally it was the species with gorgeously-coloured autumn foliage that demanded first attention, and of the great number of these the most showy were the branches of Rhus toxicodendron, the "Poison Ivy," on which, wisely, was placed a card warning visitors not to touch. Large specimens of Japanese Maples, Rhus Cotinus and Amelanchier canadensis also bore brilliant autumnal colouring. A great many berried shrubs, principally Cotoneasters and Berberis, together with the Snowberry and a number of ornamental Crabs added to the attraction. In the centre there was a large specimen of the uncommon Rhamnus alaternus variegata, while the coral flowers of Erythrina Crista-galli and the large hips of Rosa Moyesii deserved the admiration they received (Gold Medal).

Adjoining this large collection of shrubs Mr. Amos Perry arranged a fine collection of Hart's Tongue Ferns. It was said that the collection embraced 250 distinct varieties, and its extent supported that statement. Scolopendrium vul-

Digitized by Google

gare is, notoriously, the most variable of all Ferns, and on the present occasion there were to be seen almost every possible variation from the plain, sword-shaped, shining green fronds of the species. Some were so crinkled and crested as to have quite a Parsley-like appearance, others were simply crested at the tip, others, again, had gracefully waved margins to the fronds, surmounted by prettily waved tips, while a few were of rapier slenderness. But, no matter their form, all bore a family likeness and were full of charm and interest (Silver-Gilt Banksian Medal).

Another welcome exhibit amongst the sea of Michaelmas Daisies was the splendid collection of Nerines staged by Messrs. BARR AND SONS. They included several excellent seedlings, as well as a great variety of named sorts. The giant amongst them was appropriately named Hero, and it may briefly be described as being a greatly glorified Nerine Bowdenii of most lovely pink colour. It is said to produce spikes nearly 3 ft. high and, withal, is quite free from coarseness. Dainty, Prince of Orange, Sardinia and Felicity are other charming varieties, while for brilliance of colour none eclipsed that of the older N. Fothergillii major (Silver Banksian Medal).

Dahlias were shown in considerable numbers, and in very fresh condition. Mr. J. T. WEST staged many of his highly decorative small Paeony-flowered varieties, as well as Collerettes and garden Singles (Silver Flora Medal). Mr. CHARLES TURNER had, along the front of his collection of Dahlias, many of the best Pompons, and the vases of these presented a very charming appearance. He also included many of the graceful Paeony-flowered type, both large and miniature (Silver Flora Medal). Mr. J. B. RIDING set up a representative collection of many varieties, chiefly such as are of decorative value in the garden and as cut flowers for vases, and these presented a most attractive appearance (Silver-Gilt Banksian Medal). Mr. A. J. COBB had several vases of Reading Star, a glorious, scarlet-crimson variety, also a vase of Sweet, which was selected for trial at Wisley.

Roses in fresh and bright condition were staged by several growers. Mr. W. E. CHAPLIN included good vases of Los Angeles, The Queen Alexandra Rose, and Mrs. Henry Morse (Silver Flora Medal). Chief amongst the varieties shown by Messrs. F. CANT AND CO. were Emma Wright, Old Gold and Christine (Silver Banksian Medal). Mr. E. J. HICKS had a beautiful vase of the new H.T. America, with W. F. Dreer and David Lloyd George (Silver Banksian Medal). The Rev. J. H. PEMBERTON included Nur Mahal, Mary Monro and The Adjutant in his collection (Silver Flora Medal).

In a large collection of Chrysanthemums Messrs. KEITH LUXFORD AND CO. included a great many of the early-flowering varieties, which are suitable for growing as sprays. These included Verona, Dick Barnes, John McAlpine, Mrs. G. K. Thorpe and Perle Chatillonaise (Silver Flora Medal). Mr. W. F. GULLICK staged his good yellow sport from Almirante.

Michaelmas Daisies were almost unduly prominent amongst the hardy border flowers, though a great many desirable varieties were on view. Against the wall just inside the entrance Mr. H. J. JONES arranged a large collection with considerable skill: he had tall stands of such sorts as Pink Perfection, Maggie Perry, Louvain, Framfield, Elsa, Henry Adams and similar varieties were repeated in lower baskets of bloom (Silver-Gilt Flora Medal). Numbers of new and recent varieties were displayed by Mr. E. BALLARD. These included Maid of Colwall, white; Beauty of Colwall, blue; Mother of Pearl, of pearl-pink sheen, and the dwarf Little Pink Lady (Silver Flora Medal). Messrs. WATERER, SONS AND CRISP included the beautiful blue Salvia uliginosa and Elsholtzia Stauntonii with their Asters (Silver Flora Medal). Messrs. B. LADHAMS, LTD., had a number of valuable tall Lobelia hybrids (Silver Flora Medal). Hardy border flowers were also staged by Messrs. CARTER PAGE AND CO., Mr. W. WELLS, jun., Mr. F. G. WOOD, Messrs. J. CHEAL AND SONS, Messrs. W. CUTBUSH AND SONS, Mr. G. W. MILLER (Bronze Flora Medals), and Mr. H. VIGERS (Bronze Banksian Medal).

Messrs. KELWAY AND SON showed good spikes of Gladiolus, chiefly of the large-flowered hybrids (Silver Flora Medal), while Messrs. LOWE AND GIBSON had mostly Primulinus hybrids.

A goodly batch of Zonal Pelargonium (Bedding Geranium) Rossway Crimson was exhibited by Sir G. F. HADDEN, Berkhampstead (Bronze Flora Medal), Messrs. ISAAC HOUSE AND SONS again showed a collection of their perennial Scabious (Silver Flora Medal).

The Misses ALLEN-BROWN (Bronze Banksian Medal) and Mr. B. PINNEY showed collections of Violets, and Messrs. REAMSBOTTOM AND CO. had good blooms of St. Brigid Anemones (Bronze Flora Medal).

Carnations in quantity and of good quality were staged by Messrs. ALLWOOD BROS., who had large vases of Wivelsfield Apricot, Edward Allwood and Saffron (Silver Flora Medal). Mr. C. ENGELMANN included Laddie, Surprise and Saffron in his good collection (Silver Banksian Medal), while Messrs. STUART LOW AND CO. gave the most prominent position to their variety White Pearl (Silver Banksian Medal).

Fruit and Vegetable Committee.

Present: Messrs. C. J. Nix (Chairman), J. Cheal, Geo. Tinley, H. S. Rivers, G. Woodward, S. B. Dicks, W. F. Giles, J. Basham, W. H. Divers, E. A. Bunyard, Ed. Beckett, H. V. Taylor, G. Reynolds, H. N. Rawes, H. Markham, A. Metcalfe, E. Neal, A. Bullock and P. C. M. Veitch.

Several seedling Apples were exhibited for award, but none was considered worthy. A very fine culinary variety named Victory, a cross between Blenheim Pippin and Bismarck, was past its best, and as it is included in the commercial trials at Wisley, it was decided to await the results of its behaviour in the trials. A large Turnip named Golden Cross, stated to be raised between Golden Ball Turnip and Best of All Swede was considered too big for garden purposes. It is like Purple Top Aberdeen Turnip grown by agriculturists.

A large fruit of Lagenaria vulgaris was shown by VISCOUNT ST. CYRES, Walhampton, Hampshire (gr. Mr. W. Honess), and it was recommended for the consideration of the Scientific Committee. Mr. Dicks stated that certain Lagenarias were popular in America as cooked vegetables. A very showy Apple named Loddington Pippin was exhibited by Mr. G. WOODWARD. In shape and colour it somewhat resembles Worcester Pearmain, and is a good variety to succeed that sort.

Mr. A. H. WALDE, Putney, showed a fruit of Pitmaston Duchess Pear weighing one pound fourteen ounces.

Exhibits of Apples were shown by Messrs. DANIEL BROS. (Bronze Hogg Medal); Mr. E. J. PARSON (Bronze Hogg Medal), and Mr. O. M. COURAGE, Crawley (Silver Hogg Medal).

Six dishes of Morello Cherries were shown by Major-General HADDEN.

Messrs. SUTTON AND SONS were awarded a Silver Knightian Medal for a collection of Celeries, Lettuces and Celeriac. The Celeries were exceptionally fine, especially Superb Pink, Giant Red, White Gem and Giant White, the last a new variety. The Lettuces included fine heads of Heartwell, Ideal, White Heart and Sutton's Mammoth Cos.

TRIALS AT WISLEY.

THE following awards have been made by the Council of the Royal Horticultural Society to Currants after trial at Wisley:—

Red Currants.

AWARD OF MERIT.

Perfection, sent by Messrs. LAXTON BROS.

HIGHLY COMMENDED.

Comet, sent by Messrs. LAXTON BROS. and Messrs. T. HARRAWAY AND SONS; and Fox's New Red, sent by Messrs. LAXTON BROS.

COMMENDED.

Houghton Castle, sent by Messrs. T. HARRAWAY AND SONS; Southwell Red, sent by Messrs. MERRYWEATHER AND SON; Bridgeford Red, sent by Messrs. MERRYWEATHER AND SON; Littlecroft Beauty, sent by Mr. G. G. WHITELEGG. The award to Littlecroft Beauty was made for its cropping qualities, but on the understanding that this variety is suited for growing only in sheltered places.

White Currants.

AWARD OF MERIT.

White Versailles, sent by the ROYAL HORTICULTURAL SOCIETY.

Black Currants.

HIGHLY COMMENDED.

Hatton Giant, sent by Mr. H. JONES.

Trial of Spring-sown Onions.

The following awards have been made to spring-sown Onions after trial at Wisley:—

AWARDS OF MERIT.

Silver Globe, sent by Messrs. BARR AND SONS; *Anglo-Spanish* (sent as Giant Zittau), sent by Mr. HEINEMANN; *Premier*, sent by Messrs. DICKSON AND ROBINSON; *Rousham Park Hero*, sent by Messrs. WATKINS AND SIMPSON.

HIGHLY COMMENDED.

Rousham Park Hero selected, sent by Messrs. BARR AND SONS; Maincrop, sent by Messrs. DOBBIE AND CO.; White Spanish (sulphur-yellow type), sent by Messrs. COOPER, TABER AND CO.; Ailsa Craig, sent by Mr. MORSE; Cranston's Excelsior, sent by Mr. A. DICKSON; Bedfordshire Champion, sent by Messrs. WATKINS AND SIMPSON and Messrs. BARR AND SONS; Density, sent by Mr. A. DAWKINS; Golden Globe, sent by Messrs. DOBBIE AND CO.; Ohio Yellow Globe, sent by Mr. MORSE; Ohio Yellow Globe (sent as Danvers Yellow Globe), sent by Messrs. NUTTING; Up-to-Date, sent by Mr. A. DICKSON; Australian Brown, sent by Mr. MORSE; Red Flag, sent by Messrs. J. KELWAY AND SON; White Portugal (silver white), sent by Mr. MORSE; Covent Garden Silver-Skinned, sent by Messrs. BARR AND SONS; Ailsa Craig (but of Prize-taker type), sent by Messrs. COOPER, TABER AND CO.

COMMENDED.

White Spanish (French seed, straw-coloured), sent by Messrs. COOPER, TABER AND CO.; Giant Zittau, sent by Messrs. WATKINS AND SIMPSON.

Trial of Runner Beans.

The following awards have been made to Runner Beans after trial at Wisley:—

AWARDS OF MERIT.

Bounteous, sent by Messrs. DICKSON AND ROBINSON; *Prizewinner*, sent by Messrs. J. KELWAY AND SON; *Colossal*, sent by Messrs. DICKSON AND ROBINSON; *Czar*, sent by Messrs. TOOGOOD AND SON.

HIGHLY COMMENDED.

Scarlet Emperor, sent by Messrs. W. H. SIMPSON AND SONS; Sir Douglas Haig, sent by Messrs. KELWAY AND SON; Prizewinner (dark selection), sent by Mr. W. J. UNWIN; Czar, sent by Messrs. KELWAY AND SON and Messrs. W. H. SIMPSON AND SONS; White Emperor, sent by Messrs. A. DICKSON AND SONS.

Trial of Cucumbers.

The following awards have been made to Cucumbers after trial at Wisley. The following list is supplementary to that already issued:—

AWARDS OF MERIT.

Blair's Prolific, *Telegraph* (Rollison's), *Every-day*, these three sent by Messrs. BARR AND SONS; *Perfection Ridge* (Ridge var.), sent by Messrs. WATKINS AND SIMPSON.

HIGHLY COMMENDED.

Lockie's Perfection, sent by Messrs. WATKINS AND SIMPSON and Messrs. BARR AND SONS; Ideal, sent by Messrs. BARR AND SONS; Ideal, sent by Mr. DICKS; Jasper Queen, sent by Mr. G. CARPENTER, Byfleet; Sensation (Ridge var.), sent by HEINEMANN.

Digitized by Google

COMMENDED.

X L All, sent by Messrs, BARR AND SONS; Telegraph Improved, sent by Messrs. W. H. SIMPSON AND SONS.

Trial of Climbing French Beans.

The following awards have been made to Climbing French Beans after trial at Wisley:—

AWARDS OF MERIT.

Phenomene, sent by Messrs. WATKINS AND SIMPSON; *July*, sent by Messrs. J. CARTER AND Co.

HIGHLY COMMENDED.

Mont d'Or and Delicatesse, both sent by Messrs. BARR AND SONS.

NATIONAL CHRYSANTHEMUM.

The Floral Committee met at the R.H.S. Hall on Monday, October 15. A few novelties were forthcoming, but only one award was made.

FIRST-CLASS CERTIFICATE.

Chrysanthemum Dr. Jacobs.—This showy Japanese variety gained a certificate in December, 1922 as a decorative variety, and was then classed as II.i.b.; it has now been found that the variety is equally valuable as an exhibition sort, and may be grown to large size, therefore its true classification is II.i.a. The colour is crimson, with dull gold reverse. Shown by Messrs. KEITH LUXFORD AND CO.

The Executive Committee met during the evening and completed arrangements for the November show. After the usual business Mr. R. B. Leach opened a discussion on "Has the Japanese Chrysanthemum reached the limit of floral development?" A very interesting discussion ensued in which it was agreed that the limit of size had been reached but that in regard to colour, colour shades, ease of culture and fragrance, there was room for and the possibility of further progress.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

THURSDAY, October 4.—Committee present: The Rev. Cromhleholme (in the chair), Messrs. R. Ashworth, W. Heesley, J. Birchenall, J. Evans, A. Burns, A. Coningsby, D. A. Cowan, J. Cypher, A. G. Ellwood, W. Giles, A. Hanmer, J. Howes, A. Keeling, D. Losh-Thorpe, D. McLeod, F. K. Sander, E. W. Thompson, J. Whitham and H. Arthur (Sec.).

FIRST CLASS CERTIFICATE.

Cattleya Hesperus var. Duchess of York (*Enid alba* × *Hardyana alba*), a large, well-shaped flower with pure white sepals and petals, the vividly-coloured lip having a white margin and yellow throat. From S. GRATRIX, Esq.

AWARD OF MERIT.

Cattleya Dupreana alba (*Warneri alba* × *gigas alba*) from S. GRATRIX, Esq.

GROUPS.

S. GRATRIX, Esq., West Point (gr., Mr. J. Howes), staged a group for which a Silver-gilt Medal was awarded.

Mrs. BRUCE and Miss WRIGLEY, Bury (gr., Mr. A. Burns), were awarded a large Silver Medal for a group.

Messrs. J. CYPHER AND SONS, Cheltenham, were also awarded a Silver Medal for a group in variety.

GENERAL BULBGROWERS OF HAARLEM.

THE various floral committees of the General Bulbgrowers' Society of Haarlem have made the following awards to Gladioli during July and August.

FIRST CLASS CERTIFICATES.

Gladiolus Lilac Wonder. A soft pink-violet variety, with a purple blotch.

G. Quo Vadis. A light salmon-pink variety, with carmine stripes.

G. primulinus Psyche. The colour is orange-red, with a velvet blotch.

G. primulinus Vinula. A clear carmine variety.

AWARDS OF MERIT.

Gladiolus Circe. A mauve flower with a dark centre and white border.

G. Herbstzauber. A salmon-pink variety.

G. Imperator. The flowers are creamy-white to ivory-white; the stamens also are white, but the pollen is coloured mauve.

G. Mr. C. P. Alkemade. Ivory-white.

G. Red Star. A velvet-red variety, with a brown sheen.

G. Veilchenblau. A very fine mauve-coloured variety, with a clear centre.

G. nanus King of Spain. A light scarlet variety, with small white spots which have a purple border.

G. primulinus grandiflorus Flaming Sword. A clear vermilion variety, with scarlet stripes.

G. primulinus Rosaura. The colour is pink, with a vermilion centre.

G. primulinus Wilhelmina Regina. Of soft apricot colour; a small, delicate flower.

Lilium pseudo-tigrinum. The colour is orange, with purple falls.

ROYAL CALEDONIAN HORTICULTURAL

OCTOBER 2.—The ordinary monthly meeting of this Society was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. W. J. Thomson, vice-president, in the chair. A lecture was delivered by Mr. T. Cuthbert Day, F.R.S.E., on "The Chemistry of Plant Life," illustrated by lantern slides and experiments. He pointed out how the unusual and exceptional often played an important part in plant life. In the last resort, vegetation must support itself from what it can obtain from the air—water and carbon; and it was in the green leaf that the sun's rays found a meeting-place with the organic and the inorganic, and in collaboration with the chlorophyll effected the decomposition of the water and carbonic acid, and thus produced organic food for the plant and gave back free oxygen to the atmosphere.

The exhibits were:—Dahlias, from Messrs. DOBBIE AND CO., LTD.; Potatos, from Mr. COVENTRY, and a new early-flowering Chrysanthemum named T. D. Grieve, from Messrs. WOOD AND MILLIGAN, Corstorphine, which received an Award of Merit.

READING AND DISTRICT GARDENERS' SOCIETY.

THE first fortnightly meeting of the winter session of this Association was attended by 120 members. Mr. A. H. Fulkes presided. Mr. A. J. Cobb, of the University College, Reading, gave his second lecture on "Garden Roses," taking for his theme on this occasion the pruning of the various types. He said that to be successful in pruning one should fully understand the characteristics and growth of the several types, and proceeded to give some very useful hints on this branch of horticultural work, stating that a fast rule could not be laid down, as different varieties required different treatment. Situations and sorts were also ably touched upon. An interesting discussion followed, and much useful information resulted. Seven new members were elected, including Major Cadogan, M.P.

MR. A. H. FULKER presided over a large attendance of the members at the second fortnightly meeting. Mr. S. G. Smalbridge, a delegate from the Newbury Gardeners' Association, gave an interesting lecture on "Strawberries." In making a new bed he advised digging the ground two spits deep, incorporating manure with each spit and planting yearling plants in rows made 20 inches apart and 15 inches asunder in the rows. He stated that August was the best time for planting, and the duration of a bed should not be more than three years. The best varieties were enumerated, and he dealt also with diseases and manures. A keen discussion followed the reading of the paper.

In a competition for three dishes of Potatos, three distinct varieties, some excellent tubers were shown. There were eight entries, and the judge's awards were as follow:—First, Mr. D. TURNER, Coley Park Gardens, Reading; second, Mr. A. H. FULKER, Elmhurst Gardens, Reading; third, Mr. F. ALEXANDER, Kennett's Lodge Gardens, Theale.

A first-class certificate was awarded to Mr. G. TOVEY, Leighton Park Gardens, Reading, for excellent specimens of Savoys, Brussels Sprouts, and Carrots; whilst an award of merit was given to Mr. H. WYNN, Queen's House Gardens, Goring Heath, for Cos Lettuces. Mr. E. ILES, Brighton Road, Reading, exhibited some well-grown Celery from his allotment, to which the judges called special attention.

Several new members were elected.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE monthly meeting of this Society was held in the R.H.S. Hall on Monday October 8, Mr. Chas. H. Curtis presiding.

Six new members were elected. Two members withdrew interest amounting to £8 5s. 8d.; two lapsed members withdrew their deposits amounting to £8 6s. 1d.; and the sum of £51 4s. 2d., plus £10 funeral benefit, was paid to the nominee of one deceased member. The sick pay for the month on the private side came to £65 9s. 8d., and on the State side to £56 9s.; while maternity benefits amounted to £14.

The sum of £13 12s. was granted to members towards payment for dental treatment.

Final arrangements were made for the annual dinner, and applications for tickets, price 6s. 6d., should be made to the Secretary, 35, Alexandra Road, W.14.

NEWCASTLE HORTICULTURAL.

THE members of this Society held its usual monthly meeting on September 25. Mr. R. E. Richardson presided over a very large company. A paper on "Tomato Culture" was read by Mr. Lewis Richardson. The reading of the paper was followed by an animated discussion.

The society is holding a joint Apple and Chrysanthemum Show on November 9 and 10.

The annual meeting will be held on October 23.

CARDIFF GARDENERS'.

THE first meeting, for the new session, of the above Association was held on the 2nd inst., 42 members being present. Mr. H. Wilkins occupied the chair. The meeting was devoted to a discussion on Potatos in the district. The help offered to horticulture in the district by the "Advisers in Agricultural Botany," in conjunction with the University College of South Wales and Monmouth, has been accepted with enthusiasm by the Association.

TRADE NOTES.

MR. JOHN WALKER, Nurseryman, Thame, offered prizes for Onions and Carrots at the show of the Thame Agricultural Association held on September 20. Prizes of £5, £4, £3, £2, and £1 respectively, were offered for twelve bulbs of Walker's Exhibition Onion, in an open class. The first prize was won by Mr. H. Wheeler, gardener to Mrs. Jenner, Wenvoe Castle, Cardiff; the second prize by Mr. Turnham, gardener to Viscount Hambleden, Greenlands, Henley-on-Thames; the third by Mr. Douch, gardener to W. H. Gardiner, Esq., Thame Park; the fourth by Mr. T. R. Cater, gardener to W. S. Glynn, Esq., The Grange, Bletchley, and the fifth by Mr. Hazell, gardener to the Rev. R. Carew Hunt, Albury.

Mr. Walker also offered prizes for twelve Onions grown by cottager allotment holders, and the first prize in this competition was won by Mr. H. C. Jones. The prizes for Selected Intermediate Carrots were won by Mr. R. Wadham, Mr. Steeple Aston, Mr. Hazell, and Mr. Douch; the last named also won the first prize in the class for six Model Horn Carrots. The Thame Agricultural show is probably the

Digitized by Google

largest one-day show in the kingdom, and the sum offered in prizes at the recent show was £1,550.

Messrs. Geo. Monro, Ltd., are taking over the business premises formerly occupied by Messrs. T. Rochford and Sons, in order to cope with their greatly increased business in cut flowers. The premises are situated in one of the busiest parts of the market, at the Wellington Street entrance to Tavistock Street, and they adjoin Messrs. Monro's flower sales department. We understand that Messrs. T. Rochford and Sons are giving up their plant-growing business, but will retain their stands in the market proper.

THE WEATHER.

THE WEATHER IN SEPTEMBER.

The remarkable prevalence of westerly and allied winds continued during September, and northerly to easterly airs were practically absent. As a rule, land winds are frequent in September. The first eleven days were mainly very fine—the normal experience at the beginning of September—but the rest of the month was thoroughly unsettled, a curious outburst of sunshine and heat, however, occurring on the 30th, when the screened thermometers rose to 73 degrees. The mean temperature of the complete month was 54.5 degrees, from hourly statistics, and 54.9 degrees from the maximum and minimum readings, the latter value being only 0.5 degree below the average. No trace of frost was registered, even on the grass. There were 156 sunny hours, or 16¼ more than the normal number. Rain, however, fell on 21 days, or six more than usual; and the total quantity was 3.57 inches in Hesketh Park, Southport, or 0.46 inch above the average; while 3.88 inches fell in Birkdale. Wind movement was 64 miles a day above normal, and the daily range of temperature again exceptionally small. Slight thunderstorms occurred on the 1st and 25th. Gale-force of wind was attained on the 20th. Hail fell on the 22nd. *Joseph Baxendell, Borough Meteorologist, The Fernley Observatory, Southport.*

THE WEATHER IN SCOTLAND.

While the mean temperature for September was almost normal, the month was one of extremes, with a maximum of 53 degrees on the 22nd, and the genial warmth of a premature Indian summer towards the close. Rainfall was in excess of the normal, being 2.35 inches, against 2.08 inches, the month's fall and the normal being each for 14 days; the wettest day was the 18th, with 0.56 inch. The aggregate hours of sunshine were 113.9, an average of 3.8 hours per day and a percentage of 29; there were four sunless days. Barometric pressure was again rather low, the mean being 29.88 inches, the highest, 30.31 inches on the 29th, and the lowest, 29.27 inches on the 18th. The mean temperature was 53°, with a mean maximum of 60° and a mean minimum of 46°; the highest maximum of 69° was on the 30th, and the lowest minimum of 39° on the 20th. On the grass, with a mean of 42°, the lowest minimum of 35° was recorded for the 25th; again there were no nights of ground frost. The vagaries of temperature for the month are well brought out in the readings of the soil thermometer; these began at 55°, rose to 57°, fell to 50°, and rose again to 54°. The prevailing winds were south-westerly, frequently strong, with gales on the 11th and 12th. *John Davidson, Director of Studies, Training College Gardens, Mayfield, Dundee.*

ANSWERS TO CORRESPONDENTS.

Apple Allington Pippin Diseased: *Miss K. F. F.* The specimen you send is very badly affected with silver leaf disease. If it is an isolated case we advise you to grub up the tree and burn it.

Books: *G. P.* The original publishers of *Flowers of the Field*, by the Rev. C. A. John, were the Society for Promoting Christian Knowledge. Since the copyright has elapsed a new edition has been published by Messrs. C. Routledge and Sons, edited by Mr. Clarence Elliott. A good English Dictionary which we recommend is the *Concise Oxford Dictionary*, published by the Oxford University Press, price 7s. 6d.

Bulbs in the Axil of Lily Leaves: *Orchid, Fal.* Swollen buds which develop in the axils of the leaves of certain Lilies are in the nature of bulbs, and have no relation whatever to seeds. They are termed bulbils or bulbules, and may be utilised for purposes of propagation. They should be detached when ripe, and inserted in shallow seed pans or boxes, and later, when the seedlings need more room, transplanted either in other boxes or singly in small pots.

Celery with Pithy Stems: *J. C. W. and S.* The Celery is not affected by organic disease; the pithy nature of the stems is the result of an excess of nitrogenous manure at the roots and earthing up the plants too soon.

Coloured Bean: *W. S. L.* The variety is known as the Purple-Podded Bean, and is sometimes seen in collections of vegetables exhibited by traders.

Gardener's Lodge: *George.* If your housing accommodation constitutes part of your remuneration, your employer is entitled to give you notice to leave it; if you do not accede to his request, he can take ejectment proceedings in the local county court. This would take time, and even then it would be for the judge to use his discretion as to whether he should make an order for immediate possession. Gardeners and agricultural workers do not come under the Unemployment Act, and therefore are not entitled to unemployment pay.

Grapes: *C. T.* The vine may be shortened as soon as the foliage has fallen and the buds thoroughly dormant. The best work on Grape growing is *Vines and Vine Culture*, by A. F. Barron, and can be obtained from our Publishing Department, price 5s. 6d. post free.

Grapes Shrivelling: *E. R.* The berries were very imperfectly finished, and the bunch showed a little shanking, due to some check, most probably from over cropping, as you state that you have fifteen bunches on the one rod. Crop the vines lightly next season and admit plenty of air to the vinery when the weather is favourable for ventilation, to cause both berries and growth to be firmer.

Hardy Evergreen Shrubs: *F.* Practically all evergreen shrubs produce flowers, and many of them fruits. If the latter are not desired, they may be removed. Six dwarf evergreens are Berberis candidula, Cotoneaster microphylla, Daphniphyllum humile, Ruscus aculeatus, Buxus sempervirens var. myrtifolia, and Sarcococca saligna. Four evergreens about 5 feet high, suitable for your purpose, are Osmanthus Apuifolium, Ilex cornuta, Euonymus japonicus, and Berberis Aquifolium. These all grow taller with age, but may be kept dwarf by annual pruning.

Hardy Flowering Shrubs: *T. F.* Berberis stenophylla, Olearia Haastii, Veronica Traversii, Philadelphus Virginal, Diervilla Eva Rathke, and Forsythia spectabilis may be recommended for your purpose.

Hybrid Tea Roses for Bedding: *M. T.* It is not easy to name the best six Roses for bedding, but the following are all strong growing and free flowering varieties: Caroline Testout, silvery-pink; Lady Pirrie, coppery-pink; Golden Emblem, yellow; General McArthur, red, sweetly scented; Madame Butterfly, salmon-flesh, shaded rose and yellow; Mme. Jules Bouche, white, sometimes slightly tinted. Madame Abel Chatenay is also very good, while the newer Mrs. Henry Morse is very fine, but very subject to mildew. Red Letter Day is a strong grower and very free. Among the newer Roses Emma Wright, orange, is a fine bedding variety.

Lilium candidum: *Salopian.* It is probable that your Lily plants are affected with disease, most likely Botrytis, and the damp, wet condition in which they are growing would favour the complaint. Your suggestion to remove the bulbs to a drier piece of ground should be followed, and then, when the plants are established, they should be left alone, as the Madonna Lily always does best when the clumps are undisturbed for several years.

Melon Leaves Diseased: *J. A.* The Melon leaves reached us in a condition that rendered investigation of the complaint almost impossible, but we strongly suspect eelworm at the roots as the cause of the trouble. Do not grow Melons in the same pit next season if another house is available for them, and take care to sterilise the soil in which they are planted. We advise you to remove the old compost in which the plants have been grown this year to an out of the way part of the garden and bury it deeply, or if practicable sterilise it by charring.

Names of Fruits: *M. M.* Wealthy.—*G. S.* 1, Mabbot's Pearmain; 2, Norfolk Storing; 3, Sweet Lading; 4, Lincoln Pippin; 5, Twenty Ounce; 6, Bess Pool; 7, Norfolk Beefing; 8, not recognised; 9, Brabant Bellefleur.—*K. F. F.* 1, White Calville; 2, Lord Derby; 3, Old Hawthornden.—*L. M. M.* 1, not recognised; 2, D'Arcy Spice; 3, Reinette Van Mons; 4, Bramley's Seedling.—*J. B., Llandudno.* 1, New Hawthornden; 2, Lord Grosvenor; 3, not recognised; 4, Cox's Pomona; 5, Lane's Prince Albert; 6, Beauty of Kent; 7, Cox's Orange Pippin; 8, Cellini.

Names of Plants: *P. P.* 1 Wellingtonia gigantea; 2, Cupressus Lawsoniana var. Allumi; 3, Juniperus chinensis; 4, Berberis vulgaris; 5, Pernettya mucronata; 6, Thuya Lobbii; 7, Picea pungens glauca; 8, Spiraea ariaefolia; 9, Picea sp. not recognised; 10, Cupressus Lawsoniana variety; 11, Cotoneaster, probably C. applanata; 12, Cotoneaster horizontalis.—*G. R.* Polygonum amplexicaule.—*R. H. M.* Probably Golden Emblem. *K. F. F.* Specimens entirely insufficient for purposes of identification. Primroses very often produce odd flowers in a moist autumn. —*C. T.* Phlomis fruticosus.—*Mrs. M. J. W.* Cineraria maritima.—*J. B., Llandudno.* 1, Cotoneaster Henryana; 2, Olearia stellulata; 3, Hymenanthera crassifolia.—*Salopian.* Æsculus flava.—*G. W.* Myrtus communis.

White or Cream Delphiniums: *R. M. C.* Of the numerous varieties of white and cream Delphiniums, the most satisfactory are: Moerheimii, pure white, with free branching habit; Mikie Ruys, the best of the many whites, having compact, bold spikes of extra large, semi-double flowers, with yellow centre; and Deuil du Genl. Gallieni, the best milky white. All the above are free-flowering.

Communications Received.—J. H. C.—W. S. C., Hillside—W. J.—R. J. R.—C. P.—J. N.—H. W. L. L. —K. McD.—F. W.—H.—H. B.—E. H. W.—K. McD.

GARDENING APPOINTMENTS.

Mr. Henry Cameron, for the past five years Gardener to the Rt. Hon. Earl of Elgin and Kincardine, at Mertoun, St. Boswells, N.B., as Gardener to E. W. Hope-Johnstone, Esq., Raehills, Cockerbie, Dumfries-shire. (Thanks for 2s. for R.G.O.F. Box.—Eds).

Mr. Wm. Green, for the past four years Propagator at Phœnix Park, as Steward and Gardener to Michael Stephens, Esq., Coverwood, Ewhurst, Surrey. (Thanks for 2s. 6d. for R.G.O.F. Box.—Eds.).

Mr. W. Rich, for the past seven years Gardener to the late A. K. Loyd, Esq., K.C., M.P., Downs House, Steventon, Berkshire, as Gardener to R. A. Loyd, Esq., at the same address.

Mr. John E. Davies, previously Gardener to Wyndham D. Clark, Esq., and his late revered father, Godfrey L. Clark, as Gardener at the Miners' Convalescent Home, Talygarn, Pontyclun, Glamorgan, S. Wales. (Thanks for 2s. for R.G.O.F. Box.—Eds.)

Mr. Geo. Perryman, for the past five years Gardener to Sir Clifford J. Cory, Bart., Llantarnam Abbey, Monmouthshire, as Gardener to H. F. Smith, Esq., Didlington Hall, Brandon, Suffolk.

Mr. Louis Chastney, for seventeen years Gardener to the late V. D. Colchester, Esq., J.P., Norton House, Ipswich, as Gardener to F. Tibbenham, Esq., Hill Crest, Paget Road, Ipswich, Suffolk.

Mr. T. A. Botting, for the past four years Second Gardener to James Russell, Esq., Mapleton, Edenbridge, and previously at Bayham Abbey, Tunbridge Wells, as Gardener to Mrs. Norman Cookson, "The Hermitage," Newick, Sussex. (Thanks for 2s. 6d. for R.G.O.F. Box.—Eds.)

Mr. A. Carter, for the past three and a half years General Foreman at Shugborough, Stafford, as Gardener to the Hon. Marshall Brooks, Portal, Tarporley, Cheshire. (Thanks for 2s. for R.G.O.F. Box.—Eds.)

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 46.9°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, October 24, 10 a.m.: Bar. 29.2; temp., 53°. Weather—Bright.

Primula sinensis. The publication of the most recent research* into the genetics of Primula sinensis whets the appetite for more knowledge of this remarkable plant. As the result of the labours of Bateson and his pupils the mode of inheritance of most of the characters possessed by the Chinese Primrose is now well known. Previous work by Bateson and his colleagues has put the student of heredity in a position to predict with confidence what will happen when a Palm-leaved variety is crossed with a Fern-leaved variety; when a sinensis flower is crossed with a "stellata" flower; when "red stemmed" plants are crossed with green-stemmed, or dark-red stemmed varieties, and so on. The present paper fills up gaps in this knowledge and adds to it in various directions. Perhaps the most interesting facts now disclosed are those concerning the genetical relation of the several colour varieties with one another. As is known to those familiar with this plant, P. sinensis exists in a great range of colour variety. The main series of colours is—dominant white, magenta, red, blue, slaty, coral and recessive white. The dominant white variety is remarkable in that whilst its germ-cells carry the factors for colour, the body cells are prevented by reason of the presence of some inhibitor from developing colour in their flowers. The end term of the series is also white; but in this case the absence of colour in the flower is due to the absence of the colour-producing factors in the germ cells. Varieties with magenta flowers have been shown by breeding experiments to possess two factors for colour production—one for red, the other for blue, and the colour of the flower is the resultant of the action of these two factors. When the blue-producing factor is absent the flower is red, and when the red-producing factor is absent it is blue. In the light of these facts, it does not seem probable that the efforts which many plant-breeders have made to produce a perfect blue Chinese Primula are likely to be crowned with success. Even the best of blue Primulas, beautiful though they be, leave something to desire; but inasmuch as they are pure bred to the presence of the blue factor and lack the red factor, it would seem as though Nature has decreed that the azure blue which is the rare possession of certain other flowers is not for Primula sinensis. Most interesting is the discovery announced in the present communication that the good blue and the dingy slaty blue of certain varieties of Chinese Primulas are due to different states of the pigment contained in the epidermal cells of the corolla. In the true blue flowers the pigment exists in solution; but in the dingy or slaty blue it occurs in solid form—a fact which is strikingly shown in the admirable coloured plates which illustrate this paper. This discovery throws light on the nature of the red-producing and blue-producing factors. Each of these appears to possess the power of rendering soluble the pigment of the petals, the red causing it to make a red solution and the blue a blue. When both of these factors are absent, but the pigment is present (in solid form) slatiness of colour results. No less interesting than the elucidation of the genetics of colour is the description given by the authors of the use they made of their genetical discoveries to construct a new variety combining fully coloured flowers with deep claret-coloured leaves—a combination which florists had not succeeded in making. Knowledge of genetics encouraged the late Mr. Gregory to expect that this combination would turn up in one in 6,500 F_2 plants bred from parents carrying certain genetic factors. After the experiment had been continued for some years the long-expected plant arrived and from it the remarkable new variety, Etna, exhibited by Messrs. Sutton and Sons in 1921, was derived. The paper concludes with an account of the history of Primula sinensis; but it unfortunately leaves the knowledge of the origin of this remarkable plant shrouded in mystery. The claims of Wilson's Primula from China, now known as P. calciphila, to be the wild prototype are dismissed. But where the Chinese Primula grew before it was imported by Captain Richard Reeves, soon after 1819, "from gardens" at Canton, remains unknown. The authors are not disposed to regard P. sinensis as of hybrid origin, and yet, though China has been well explored, no wild P. sinensis has been discovered. Soon after its advent in this country, the Chinese Primrose began its spectacular course of variation, a second importation of seeds occurred a little before 1826, when seeds were brought by Mr. Potts, and already, in 1826, Lindley described stellata and sinensis varieties. It appears certain that the originally-imported plants possessed already all the dominant characters, sinensis habit of flower, Palm leaf and magenta colour. Since its arrival, P. sinensis has developed others, the dominant white flower, the origin of which is unknown, and the white eye introduced by MM. Vilmorin about 1902. In the course of its sojourn here, P. sinensis has sported in various directions. Giant forms both of sinensis and of stellata type have appeared, and with respect to the latter it may be of interest to mention that large-petalled stellata flowers, massive enough to be called Giants, now being grown by Messrs. Sutton, originated with the present writer in the course of a series of selections of normal-sized stellata flowers exhibiting supernumerary petals—six instead of the normal five. Though variation by gain of factors appears to have been rare, variation by loss has occurred frequently. The recessive stellata form appeared early. Long-styled forms (which are recessive to thrum-styled) also arose long ago, and for some reason or other were so much preferred that the thrum-eyed variety became extremely rare. Duchess, very beautiful, though apparently somewhat unstable, appeared long ago. In it the dominant white is, as it were, broken up, being confined to the periphery of the corolla, the inner area of which is of a reddish colour. Fern-leaf also appeared early, and at late periods, Oak-leaved, Ivy-leaved and crisped forms have made their appearance. Blues, which, as described already, are recessive to other colours, and the large yellow eye—the Primrose-green eye—are later acquisitions of a recessive nature. So, too, is Coral, a plant which arose with Messrs. Sutton as a colour sport from Crimson King. What may be the antecedent history of this Melchizedek among plants? Without known father or mother, with no wild representative, unable, so far as may be discovered, to cross with any other species! Is it unique among plants in its remarkable genetic history, or is some hybrid origin reflected therein? These are questions it is impossible not to ask, and, unfortunately, as impossible to answer.

* Genetics of Primula sinensis. By the late R. P. Gregory, Miss D. de Winton and W. Bateson. *Journal of Genetics*. 13, 2. August, 1923.

Leeds Chrysanthemum Show.—The Leeds Paxton Society will hold a Chrysanthemum show in the Town Hall, Leeds, on November 16 and 17, in aid of the funds of the Leeds General Infirmary. Substantial prizes are offered in fifty-six classes, and in addition to Chrysanthemums there are classes for fruits and vegetables and two for children attending the elementary schools of Leeds. The latter are for dried mounted specimens on nature study in relation to wild flowers and insect life, and for an individual collection of leaves and berries or plant life and insects. Gold, silver, and bronze medals are offered for trade exhibits, and prizes of £10, £6 and £4 respectively are offered in an open class for twenty-four Japanese Chrysanthemums. In a local class for a group of Chrysanthemums, the prizes offered are £6 6s., £4 4s., and £3 3s. respectively. We understand that an excellent exhibition is anticipated. The secretary is Mr. R. B. Russell, 45, Great George Street, Leeds.

Southport Floral Fete and Water Carnival, 1924.—The proposal to hold a big Floral Fête and Water Carnival in Southport next August was very favourably received by the Parks and Foreshore, and the Advertising and Band Committees of the Southport Corporation at their recent meetings. As already announced, it is intended that the Fête shall be on the lines of the famous Shrewsbury Flower Show, and that it shall be held during the week after that event. Although the dates have not been definitely fixed, they will probably be Wednesday, Thursday, and Friday, August 27, 28 and 29. The exhibits will be housed in a huge marquee covering about an acre of ground in the Victoria Park, alongside which runs Southport's famous half-mile flower border—a most appropriate setting for a Floral Fête. It is proposed to offer prizes to the value of about £1,500, including nine silver challenge trophies, four or five of which will be of the value of

Digitized by Google

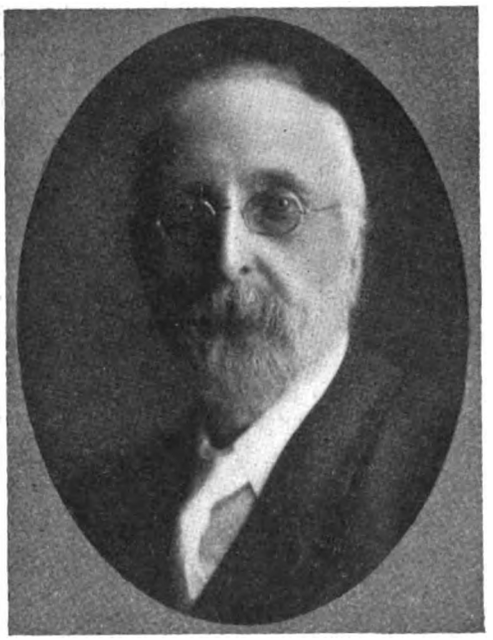
£50 each, and the remainder of the value of £25 each. Three of the trophies have already been offered by the Southport Amusements, Limited, and Councillors Winterbottom and Lean. Although the schedule has not yet been definitely decided upon, the challenge trophies will probably be allotted to classes for rock or water gardens, fine foliage plants, Carnations, fruit, hardy flowers, Roses, Sweet Peas, Dahlias, and early-flowering Chrysanthemums. The Horticultural Society of the London, Midland and Scottish Railway (Northern Division), which last August held a successful flower show in the Victoria Park, Southport, will be invited to hold their 1924 show in conjunction with the Southport Floral Fête. The proposals include the holding in the evenings of a Water Carnival on the Marine Lake adjoining the Marine Parks, concluding with displays of fireworks. The inauguration of a huge annual floral fête during the Mayoralty of Mr. Alderman Aveling (who for the past three years has been the Chairman of the Parks and Foreshore Committee) will be peculiarly fitting, and should certainly do much to enhance Southport's reputation for splendid floral displays.

National Sweet Pea Society.—The annual general meeting of the National Sweet Pea Society will be held in the Lecture Room, Royal Horticultural Hall, Vincent Square, Westminster, London, S.W., on Tuesday, October 30, 1923, commencing at 2.15 p.m.

Bayley-Balfour Memorial Garden.—A short time before he retired from the position of Regius Keeper of the Edinburgh Botanic Garden, the late Sir Isaac Bayley-Balfour had in mind the establishment of a garden for the cultivation of Rhododendrons and other newly imported plants from China, and hoped that such a garden would be established on one of the estates acquired by the Forestry Commission. Later, and after his retirement from Edinburgh, a site was selected in Glenbranter Forest, Argyllshire. This received his hearty approval, and by arrangement between His Majesty's Office of Works and the Forestry Commission consignments of plants were sent there from the Edinburgh Botanic Garden. We learn that an area of fifty acres has been definitely set apart for this garden, and will be under the superintendence of the Regius Keeper of the Edinburgh Botanic Garden, and the hope is expressed that it will be called the Bayley-Balfour Arboretum or Bayley-Balfour Memorial Garden. It is also suggested that there should be a rest house for the use of visitors to Glenbranter, but the size of the building will be subject to the amount of funds forthcoming. In any case, endeavour will be made to provide simple accommodation for visitors who wish to spend several days at Glenbranter. We sincerely hope that this proposal to commemorate Sir Isaac Bayley-Balfour will appeal to those who entertained a high regard for his great ability. A small executive committee has been appointed to carry out the proposals, consisting of Sir John Stirling Maxwell, Pollok House, Pollokshaws; Professor W. Wright Smith, Royal Botanic Garden, Edinburgh; Mr. F. R. S. Balfour, Dawyck, Stobo; and Mr. John Sutherland, 25, Drumsheugh Gardens, Edinburgh, who is acting as honorary secretary and treasurer, and to whom subscriptions should be sent.

Coming-of-Age Celebration of the Reigate Gardeners' Association.—To celebrate the completion of twenty-one years' work, the Reigate and District Gardeners' Mutual Improvement Association held a coming-of-age dinner at the Warwick Hotel, Redhill, on Friday, the 12th inst. Sir Jeremiah Colman, Bt., the President of the Association, presided, and there was a splendid attendance of members and friends. In proposing "Continued Success to the Association," Sir Jeremiah Colman observed that the Association was one of the principal institutions of the neighbourhood, and, in addition to furthering and encouraging horticulture and extending a knowledge of horticultural procedure, it came forward as a body and made a collection for the East Surrey Hospital. The result was a splendid success, and, though there still remained a considerable sum necessary to endow a bed at the Hospital, he was sure the Society would soon set to work to complete the noble sum of £1,000. Sir Jeremiah referred to the fine work done on behalf of the Association by the first Chairman, Mr. W. P. Bound, to whom the members owed a deep debt of gratitude, and to Mr. J. Collier, the present Chairman. Continuing, Sir Jeremiah said that, now the Association was twenty-one years of age, and as he was one of its fathers, doubtless the members "would be able to part with control and look for another President," but the meeting emphatically vetoed Sir Jeremiah's implied suggestion of retirement. Brig.-Gen. G. K. Cockrill, the member of Parliament for the division, Mr. J. Collier, Alderman Crosfield, Mr. W. Burgess, Mr. P. Sherlock, and Mr. W. Rose (Hon. Secretary) were other speakers on this auspicious occasion.

Mr. B. D. Jackson.—Mr. Benjamin Daydon Jackson, the popular Secretary of the Linnean Society, is well known to many of our readers, if not personally, at least through his numerous writings on botany and his work in connection



MR. B. DAYDON JACKSON.

with the premier botanical Society of the country. Mr. Jackson is a native of London, and, like many others who have attained eminence in some special branch of science, he commenced the study of plants as a result of a special happening, for he became interested in the subject when recovering from an illness at a country home in Sussex in 1865. He quickly became absorbed in botany and in a few years—1876—he published his work on John Gerard, under the title of *A Catalogue of Plants Cultivated in the Garden of John Gerard*, a review of which, extending to over three columns, was given in *Gard. Chron.*, July 8, 1876, and the notice concluded with the hope "that Mr. Jackson may be induced to continue his researches into the history of botany in England, and that others of our early writers may receive as much attention at his hands as he has here bestowed upon John Gerard." Before this, in January, 1868, he was elected a Fellow of the Linnean Society; in May, 1880, he was appointed secretary and became general secretary in 1902. It is to such men as Mr. Daydon Jackson that the Linnean Society owes its pre-eminence among the learned institutions of this country. A response was soon made to the wish cited above, for in 1877 he published *Turner's Life and "Libellers,"* and other works issued from his pen include *Guide to the Literature of Botany*, in 1881; *Vegetable Technology*, in 1882; General Index to *Journal of the Linnean Society*, 1888; *Glossary of Botanic Terms*, 1900; *Life of George Bentham*, 1906; *Index to the Linnean Herbarium*, 1912; and he also edited the late A. R. Fryor's *Flora of Hertfordshire*, and the late C. B. Clarke's *New Genera and Species of Cyperaceae*, 1908, and *Illustrations of Cyperaceae*, 1909. But perhaps Mr. Jackson's most monumental work was the editing of *Index Kewensis*, under the direction of the late Sir Joseph D. Hooker. This occupied Mr. Jackson and his assistants fourteen years, and he was also responsible for the Supplements, 1886-1895. Mr. Jackson is a Knight of the Polar Star and Hon. Ph.D. of Upsal University, honours which prove that his abilities and contributions to botanical history and knowledge are recognised far beyond our own shores.

Mr. A. C. Smith.—We learn with very great regret that Sir Henry and Lady Samuelson have decided to close their beautiful establishment at Hatchford Park, Cobham, Surrey, owing to the prolonged illness of the former. This releases Mr. A. C. Smith, who for the last ten and a half years has had charge of the estate, and whose long and varied experience has fitted him for any important position of a similar character. Our readers will remember that Mr. Smith was formerly Assistant Superintendent of the Royal Horticultural Society's Gardens at Wisley, and previous to that was in charge of the gardens at Lyndhurst, Haywards Heath, and for six years gardener and forester at Edenhall, Langwathby, Cumberland.

New Assistant Director of the Glasgow Parks.—We learn with pleasure that Mr. William Besant, until recently Curator of Kelvingrove Park, Glasgow, has been appointed Assistant Director of Parks and Open Spaces, under the Corporation of the City of Glasgow.

French Chrysanthemum Society.—The annual congress of this society will take place at Limoges from the 4th to the 8th November. It will be held in conjunction with an International Horticultural Exhibition organised by the local horticultural society. The schedule is divided into eight sections, with classes for new seedling Chrysanthemums, pot plants and cut blooms, fruit and fruit trees, market gardening, ornamental trees, shrubs and plants of various kinds, and floral art and industries. An art section will also be a feature of the show. The festivities include on November 3 a reception at the Town Hall. On November 4 judging will commence early, followed by a luncheon and the opening of the show and congress. In the evening of that day a banquet will be given to the jury and others connected with the gathering. On November 5 there will be a further meeting of the congress in the morning, then an excursion and luncheon at Aixe. Places to be visited are Solignac, the Abbey, the Chalusset Towers, and the farm of M. Le Play. In the evening there will be a performance at the municipal theatre. The morning of November 6 will be devoted to a visit to the various local porcelain, enamel, and other factories for which Limoges has so long been noted. The agenda for the congress includes such subjects as the Botanical Aspects of the Crown and Terminal Buds; Progress in Fertilisation; Selection of the Best Varieties, Old and New, for Market Plants; Diseases; Sports and the Question of International Priority Regarding Them; and Propagation Other than by Seed. Medals will be awarded to the best papers. Further information may be obtained from Mr. Harman Payne, Foreign Secretary, N.C.S., 195, Wellmeadow Road, S.E.6.

Markets Harvest Festival.—On Sunday, the 21st inst., the interesting annual harvest festival of the Billingsgate and Leadenhall Markets was held at St. Dunstan's-in-the-East Church, Great Tower Street, London. Flowers, fruits, corn, and fish-nets were used to decorate the church, while on a long table the gifts of the market traders were displayed, including a great variety of fish, poultry, fruits, and vegetables. At the close of the service, conducted by the Rev. A. G. West, the gifts were sent to Guy's Hospital.

Digitized by Google

Agricultural Conference at High Leigh, Hoddesdon.—The War and Social Order Committee of the Society of Friends has arranged a Conference, to be held on November 2-5 inclusive, at High Leigh, Hoddesdon. The subject for discussion is "The Problem of Agriculture." Dr. B. A. Keen, Assistant Director, Rothamsted Experimental Station, will discuss "The Historical Aspect of Agriculture"; Mr. Montague Fordham will place "The Economic Aspect of Agriculture" before the Conference; while Mr. J. Hunter Smith, Director of Hertfordshire County Council Agricultural Institute, will open a discussion on the "Possibilities of Development in Agriculture"; and on Sunday evening, November 4, Mr. J. Nugent Harris will deal with "The Human Aspect of Agriculture." The fees for this Conference, from Friday evening, November 2, to Monday morning, November 5, including meals will be £2 2s. The Conference programme will include an excursion to Welwyn Garden City in the afternoon of Saturday, November 3. Full particulars may be obtained from Miss M. E. Thorne, Devonshire House, 136, Bishopsgate, E.C.3.

New Zealand Plants.—Mr. Herbert Baillie, of Wellington, N.Z., informs us that a new edition of Cheeseman's *Flora of New Zealand* is nearly ready for publication, and that Dr. Cockayne, F.R.S., is publishing what should be a very useful book for gardeners, *The Collection and Culture of New Zealand Plants*. Dr. Cockayne is an enthusiastic gardener in addition to being a noted botanist.

Chrysanthemum Shows in the London Parks.—Exhibitions of Chrysanthemums are now open in the following London County Council Parks: Battersea Park, Finsbury Park, Southwark Park, Victoria Park and Waterlow Park.

Appointments for the Ensuing Week.—Tuesday, October 30: Royal Horticultural Society's Committees meet (two days); Bournemouth Horticultural Society's show (two days). Wednesday, October 31: Eastbourne Horticultural Society's show (two days); Croydon Chrysanthemum Society's show; Highgate and District Chrysanthemum Society's show (two days); Haywards Heath and Mid-Sussex Horticultural Society's show; Mitcham, Tooting and District Horticultural Society's meeting; Lewes and District Horticultural Society's meeting. Thursday, November 1: National Chrysanthemum Society's show (two days); Taunton and District Chrysanthemum and Fruit Society's show. Friday, November 2: Corn Exchange Chrysanthemum show. Saturday, November 3: Blackburn and District Horticultural Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Growing Plants in Nutshells.* Those who are interested in the nutshell culture of plants will find the present time favourable for commencing operations. Choose for the purpose some nice little short-jointed, half-ripened cuttings, which are generally to be found on branches that have been much exposed to the wind. The remark applies to Verbenas, Roses, Pelargoniums, Fuchsias, or other favourites. Pinch off the bottom leaves, and insert the cutting about half way up in silver sand. Place them in a little bottom heat, and tilt up the light so that they may enjoy a full current of air, and keep them moderately dry. When they have made their first roots, which will be in about three weeks, take them out carefully and plant them firmly in the nutshells for their winter quarters. The soil best adapted for plants in nutshells is a thoroughly decomposed vegetable manure, mixed with silver sand. A single, or what is called a one-light frame, will be quite sufficient to accommodate a moderate collection of plants. The frame should be four feet by three, and about two feet deep. *W. P., Gard. Chron., October* 21, 1848.

Publications Received.—Research and Advisory Work: *Journal of the South-Eastern Agricultural College*, Wye, Kent. No. 23. Price 2s. 6d.—*Studies in Soil Acidity.* By J. L. Sager. University Press, Cambridge.

THE ALPINE GARDEN.

THE CREEPING ROSEMARY.

Rosmarinus prostratus, as the prostrate form of the common Rosemary is called, is a most delightful shrub for a dry wall, sunny ledge, or any other warm spot where the soil is light, and there is full exposure to the south or west. It is quite a fast grower, soon covering a considerable space with its pretty, arching branchlets, or closely hugging the rock face, and it flowers profusely. Here we can usually look forward to a good show of blossom in autumn in addition to that of spring, and the pale blue flowers are fully as large, if not often larger, than those of the type. The foliage of R. prostratus is a peculiarly fresh and glossy green, which looks well in the rock-garden at all seasons. Though not hardy, this variety will often survive an average winter in places not noted for a mild climate, whilst in the south and west it is rarely affected. As a matter of fact the lowly, creeping habit of R. prostratus is distinctly in its favour in bleak districts, for not only is it thus less liable to injury by frost and cutting winds, but it may be much more easily protected than the ordinary Rosemary. *N. Wales.*

RUTA PATAVINA.

Not many of the Rues are choice enough for the ordinary rock garden, though they often look well when kept dwarf by pruning, with their blue-green leaves and heads of small flowers. There is, however, one which deserves some consideration from the alpine gardener. This is Ruta patavina, which is rather trailing but does not grow usually more than six inches high. It looks quite well hanging over a stone, with its bluish-green foliage and starry flowers of pale yellow. The plant seems to be hardy in most places if planted in very poor, hard, dry soil and in a sunny situation. It may be propagated from seeds or cuttings, the latter method being that generally adopted. The planting of this Ruta is best done in the spring. *S. A.*

CHRYSANTHEMUM DR. JACOBS.

When this variety was first exhibited by Messrs. Keith Luxford and Co., late in 1922, the flowers shown were of what is generally known as decorative size, and the Floral Committee of the National Chrysanthemum Society granted it a First-class Certificate and classified it as a medium-sized variety (II.l.b.). As a result of this classification and its usefulness for providing richly hued blooms of decorative size, the variety has been acquired by several growers who supply the market; moreover, treated as a decorative variety it flowers quite late in December. On October 15, however, Messrs. Luxford exhibited the variety in exhibition form and thus placed the Floral Committee of the National Chrysanthemum Society in an unusual position, because obviously Dr. Jacobs is a large-flowered exhibition sort and an early-flowering one at that, but one which, cultivated in bush form, becomes a very useful late-flowering decorative sort. In short, the difference is one of cultivation rather than of type.

The Floral Committee confirmed its previous award of a First-class Certificate, but altered the classification to II.l.a. Dr. Jacobs is a crimson variety with dull gold reverse.

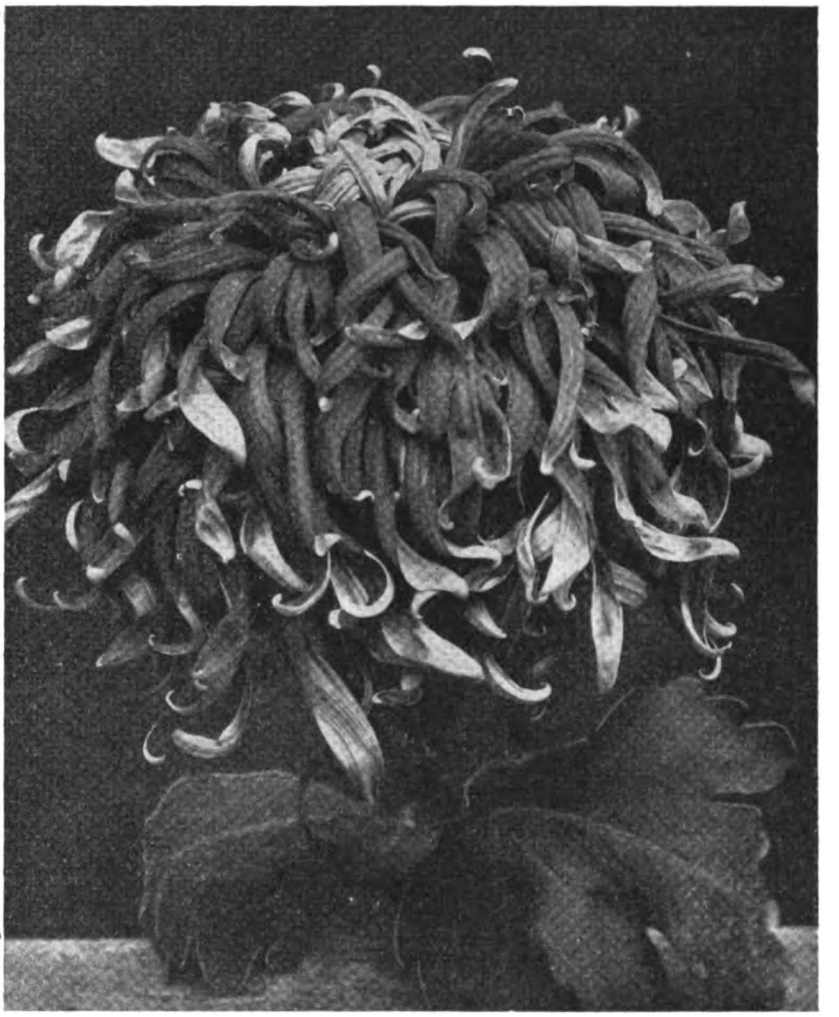


FIG. 89.—CHRYSANTHEMUM DR JACOBS: NATIONAL CHRYSANTHEMUM SOCIETY'S FIRST-CLASS CERTIFICATE, OCTOBER 15, 1923 (SEE P. 241).

The Week's Work.

THE ORCHID HOUSES.

By J. T. Barker, late Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

Laelia monophylla.—This little gem among Laelias has bright scarlet flowers, yet the plant has always been considered a difficult subject. When well established and well rooted, and not allowed to over-flower itself, it may be kept in good health for a long time. This Orchid should be grown in small, well-drained pots, in a mixture of Osmunda and A1 fibre. The fibres should be cut into moderately fine portions, and the potting done with moderate firmness, in such a way that when the plants are watered, the surplus moisture will pass away as freely as through a sieve. A good plan is to elevate these small plants among, or above, those of Miltonia vexillaria, the plants thus obtaining the same cultural conditions as that species.

Dendrobium.—The deciduous section of this genus includes many members which produce their flowers early in the winter, and the plants will by this time have fully completed their season's growth. Such plants should now be placed where they will receive all the light possible, in a drier atmosphere, reducing the temperature gradually to a minimum of about 55° to 58°. The flowering of these plants depends entirely on the proper resting and consolidation of the growths, therefore it is essential to take the greatest pains to attain this end. Backward plants, with those that have started to develop a secondary growth, should be given every encouragement to complete their season's growth at the earliest possible date. These remarks apply to all sections of this large and beautiful family, as growth made in the dull days of winter is always of an unsatisfactory nature. The tall-growing species, such as D. Dalhousieanum, D. moschatum, D. fimbriatum, with D. Brymerianum, and their varieties, and several other species of a similar nature, are mostly late in completing their growths, therefore these plants should be afforded liberal treatment until the terminal leaf is visible. These evergreen species, with D. densiflorum, D. Farmeri, and others of this section, should be grown in the warmest divisions at all seasons. During the winter, when the temperature is lower, and the plants are resting, infrequent waterings will suffice to keep the pseudo-bulbs plump and the roots healthy. An excessively dry condition is as harmful as keeping the plants too moist, therefore great care is necessary in watering these Orchids in winter.

D. Phalaenopsis Schroderianum.—Plants of this Orchid now coming into bloom should be afforded slightly more heat and more ventilation to assist the flowers to withstand fog, which in the vicinity of large towns has a pernicious effect upon them. Whilst the plants are carrying their flower spikes, a moderate supply of water to the roots should be afforded, but after the blooms are removed, sufficient moisture only is required to keep the pseudo-bulbs from shrivelling. During the plants' inactive period they are better for being grown in a slightly lower temperature and given a thorough rest.

THE FLOWER GARDEN.

By C. Turner, Gardener to Emily, Lady Ampthill, Ampthill Park, Ampthill, Bedfordshire.

Storing Tender Plants.—Cannas, Dahlias, Hyacinthus candicans, Gladioli and Salvia patens are a few of the plants which require to be lifted from the beds and stored for the winter. It is not so much that their safety depends upon them being taken up—for the plants would survive average winters where they have grown, especially were they covered with leaf-mould or sand—but their removal makes it much easier to cultivate the ground, and a fresh site can be allotted the roots next season if desired. Lay the tubers of the Salvia on soil and stand the Cannas and Dahlias on the floor of a cold, frost-proof house or cellar, but suspend the two other kinds in bags—having first well dried bulbs and corms. Commelina coelestis should also be taken up and stored in dry, sandy leaf-mould in a place safe from frost. Success in wintering this plant does not always follow, but it is easily raised from seed sown in the spring should the tubers fail.

Amaryllis Belladonna.—Where this bulbous plant succeeds, no autumn flower is more lovely—but the blooming of the plant is somewhat erratic. The bulbs may be planted now and on through the winter. Choose a very warm position for the plant, such as against the south wall of a dwelling-house or greenhouse. The soil in which it is planted should be deep, light and rich. Protect the bulbs in winter with a covering of Bracken Fern.

Lawns and Verges.—Just when the mowing and cutting of lawns and grass verges should cease for the season depends somewhat on the advent of frost and settled cold weather. However, I like to cut the grass as late as possible in autumn in order that there is no excess of growth to get tough by springtime, as will be the case where mowing has ceased too soon. The above evil is, of course, of no moment where scything of lawns is practised in spring before mowing is begun, but such a preliminary is not possible in every garden. After the lawns have received their final trimming, the mowing machines and shears should be thoroughly cleaned and well coated with thick oil to keep them in good order. Any repairs and overhauling necessary to the machines should be attended to early in the New Year so that they may be in perfect order when mowing begins again.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to J. A. Bennett, Esq., Woolverstone Park Gardens, Ipswich.

Melons.—The fine weather of September had a beneficial effect on the Melon crop, materially assisting the growth both of plants and fruits. With the advent of shorter days and waning sun-heat the moisture in the house should be reduced to a minimum. The soil should be kept moderately dry. After the fruits commence to colour, watering the roots should cease and a warm, dry atmosphere be maintained in the house to assist the fruits to mature. Melons should be cut on the first signs of cracking away from the stems, afterwards allowing them to remain in the house for two or three days to fully mature. A little air may be admitted during the warmer part of the day, but the house should be closed early in the afternoons. Where the bottom heat is under control, afford a steady temperature of 80° until the fruits are cut.

Cucumbers.—The crop of Cucumbers from plants in frames stood on hot beds will soon be over, and the supply will have to be continued from plants in the Cucumber house. In order to obtain the best results from these plants for so long a time as possible they should be cropped lightly; all deformed and unnecessary fruits should be removed while they are quite small. During mild weather only moderate forcing should be practised, otherwise the growth will be weak. The bed of soil should, however, be kept sufficiently warm to obviate a check to the roots, and the temperature of the house should be well maintained in order to ensure healthy growth. Allow the growths ample room, and regulate and stop them once a week. Afford the roots a top-dressing of turfy loam enriched with a liberal sprinkling of bone flour and wood ash: the top-dressing should be applied in small quantities on frequent occasions. Plants intended for successional cropping may be grown in accordance with the demand for Cucumbers, not permitting them to bear until they have acquired strength, and the earlier plants show signs of exhaustion. The ventilation of these houses needs to be done with care, and air should be afforded only during the brief portion of the day when the sun shines. The syringing of the plants should likewise be modified to suit the season, discontinuing it, except once daily on warm days, a damping of the floors, walls and other bare surfaces taking its place. Damping is necessary to keep red spider and thrips in check. If thrips or aphis appear on the plants, recourse should be had to fumigating with the XL-All vaporiser. If the plants are attacked with mildew, make use of the sulphur vaporiser before it spreads all over them: after applying the sulphur the atmosphere of the house should be kept drier for two or three days.

THE KITCHEN GARDEN.

By R. W. Thatcher, Gardener to Mark Firth, Esq., Carlton Park, Market Harborough, Leicestershire.

Mustard and Cress.—Both Mustard and Cress may now be sown in boxes under glass if needed. Use good, loamy soil, and sow the seed on the surface, lightly pressing is down into the soil, but not covering it. Water and shade the seed boxes until the plants commence to grow.

The Frame Yard.—Old hotbed material in the frame yard should be cleared out to make room for a fresh supply of fallen leaves. The material should be wheeled to ground that is heavy and of a clayey nature, mixed with ash from the garden fire, and used to lighten the land and render it more workable. Heavy land intended for Potatos will be greatly benefited by a good dressing of this compound. Where farmyard manure is difficult to obtain, old hotbed material will serve to top dress Asparagus beds, and much of it may be used in shrubberies with good effect. Where Oak or Beech trees were used in conjunction with stable litter for making hotbeds, it will be advisable to reserve a goodly portion for potting purposes, and this may be neatly stacked to draw upon as required. It may also be used later on for mixing with loam for growing early vegetables in frames.

Onions.—The Onion crop should by now be under cover, but if the bulbs have not yet been lifted, this should be done forthwith, the loose skin taken off and the bulbs placed in frames to ripen them. Cut the tops off close to the bulbs, and either string the latter on canes or store them on shelves in a dry, frost-proof shed.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Polygala myrtifolia var. grandiflora.—This useful shrubby plant for the cool greenhouse is easily propagated at this season by means of half-ripened shoots, inserted in sandy soil, and stood under a bell-glass in a cool greenhouse. The plants succeed in a compost of light loam, with the addition of a little fibrous peat, and sand. They should be potted fairly firmly, and the young plants should be pinched several times to induce a bushy habit.

Berberidopsis corallina.—This native of Chili is a beautiful plant and hardy on walls in the south and west of England; but in the colder parts of the country it is a fine subject for the cool greenhouse, where it is seen to the best advantage if it is planted out and trained against a back-wall; it loves a cool position, as it is somewhat subject to attacks of red spider. It is easily propagated at this season by means of cuttings, or again during the spring and summer. The cuttings root readily under a bell glass in a cool greenhouse.

Rhododendrons for Forcing.—Numbers of Rhododendrons are suitable for forcing. R. Rosa Mundi, a small growing variety, may be had in flower by Christmas, while Prince Camille de Rohan is a good type for early work; in fact, all the varieties of R. caucasicum parentage naturally flower early and force readily. R. praecox is very charming for early forcing; as also are R. emasculum and R. mucronulatum.

Digitized by Google

Watering.—With the advent of short, dull days, watering should be done with extra care, remembering that plants are less likely to suffer from drought than from being kept too wet. Watering is best done in the mornings at this time of the year to allow superfluous moisture to dry up before night. As more fire heat will be necessary care should be taken to keep the walls and floors in the neighbourhood of the waterpipes well damped.

Tropaeolum tricolorum and T. Jarrattii.—These are very pretty Nasturtiums for the cool greenhouse, and good specimens may be obtained by growing four or five tubers in a 10-inch pot. The tubers may be potted now or as soon as they are obtained. When the slender shoots are a few inches high they should be supported by slender twigs, while light sprays of Hazel, some 3 feet in length, should be placed in the pots for them to climb over.

HARDY FRUIT GARDEN.

By A. J. Hartless, Gardener to Major J. F. Harrison, King's Walden Bury, Hitchin, Hertfordshire.

Planting.—The preparation of land for the reception of fruit trees or bush fruits obtained from nurseries should be completed. It is important to choose a time for planting when the soil is in a proper condition as to texture and moisture. Should the ground be very moist it is better to heel the trees in until the conditions are drier. Ramming the soil, which is very necessary to secure a proper root-system, will be detrimental to root action if the land is "sticky." The thorough firming of the soil on which the tree rests and also that placed above the roots is essential on light soils. Damp, low-lying parts of the garden should not be selected for fruit trees except for Black Currants. It is far better to plant on high ground, using quick-growing hedges or belts of trees as wind breaks. The Myrobalan Plum is often used for the making of hedges, but it does not appear to me to be wise to use a subject so nearly related to fruits, and therefore open to be attacked by the same insect and fungous pests. The branches of newly-planted trees should be shortened to half their length in the early spring. Late-planted trees should be similarly dealt with the following autumn. Cherries are not usually pruned in the first year of planting, but Peaches and Nectarines should be cut back in March whether autumn or spring planted. I would again emphasise the importance of securing trees on the most suitable stocks. The true broad-leaved English Paradise finds most favour with growers as an Apple stock. Trees bought from doubtful sources, often in markets, as a rule prove disappointing. Those worked on the Crab stock are suitable as standard orchard trees. For planting in soils of average texture Pears should be worked on the Quince, but in the case of very light soils they should be on the Pear stock. Any tendency of the trees to make coarse and unfruitful growth should be counteracted by root-pruning. Apricots, Peaches and Nectarines growing in shallow soils will need a renewal of soil immediately the trees show signs of exhaustion. An annual dressing of lime or lime-rubble will be of great help to stone fruits. Gooseberries, Currants and Loganberries raised from cuttings inserted last autumn need transplanting.

General Remarks.—The constant rains have made it difficult to keep the ground clear of weeds. Every effort should be made to get this work done before the winter sets in. The gathering of main crop Apples and Pears should now be near completion. Birds have been especially destructive to fruits this year, and it has been necessary to use muslin bags in these gardens to protect the few we had. Unfortunately a large number of Apples dropped before they appeared to be really ripe. Bramley's Seedling, Newton Wonder, New Hawthornden and a few other standard varieties have yielded good crops. Although not quite up to the usual size, Cox's Orange Pippin has also given a fair yield. All fruit appears to be less free from scab than usual. Grease banding should be completed by this date. Lime rubble, etc., accumulated last month is ready for use in planting operations. Late-planted Strawberries are getting established in the soil and after frosts the soil about them should be trodden lightly. Where Apricots are grown in cool glass cases, and the structure allows, it is a good plan to remove the long front lights in order to expose the trees to the weather for the next few weeks.

FLORISTS' FLOWERS.

SWEET PEAS UNDER GLASS.

I think Sweet Peas are not grown so extensively under glass as they should be. They are popular and decorative, and with a little extra care first-class blooms may be obtained in April, or early May, at a time when they are much appreciated. To secure such early flowers seed should be sown as early in October as possible, although I have had excellent results from sowings made at the end of that month. I sow the seeds in large 60-sized pots, and use a compost of three parts good loam, passed through a half-inch mesh sieve, and one part leaf mould, adding some burnt soil, lime rubble, or coarse sand. Fill the pots firmly, two-thirds full, placing five seeds in each, covering them and watering them. If possible, place the pots in a propagating case, in a cool house, with a temperature of 50° to 55°. Cover the pots with paper until the seedlings appear; they should then be brought to the light gradually, and afterwards placed on a shelf near the glass in a cool house, a Carnation house being very suitable for the purpose.

After the third leaf appears, the growing point should be pinched from each plant, so as to encourage strong shoots from the base. If desired, two shoots may be allowed, otherwise retain one only. Careful watering at all times is necessary, especially after pinching. When sufficiently recovered the plants should be potted singly into large 60-sized pots, using a similar compost to that already advised, but with the addition of a little bone meal. The loam also may be somewhat coarser. Syringe the plants overhead on fine days, pinch out all tendrils as they appear, rub out all side shoots as early as possible, and place a supporting stake to each plant.

Later treatment depends on the conveniences available for indoor culture, but undoubtedly the best method is to plant out Sweet Peas in a cool Peach or Tomato house, providing they can be grown near the light, and not detrimental to other occupants. Failing this they may be grown on, potted into 32-sized pots, and finally into 10-inch pots.

If planting out is contemplated, a trench should be taken out sometime previous to planting, 18 inches wide and about 2 feet 6 inches deep. Care should be taken not to mix the subsoil, if of a gravelly nature, with the top spit.

Fork up the bottom of the trench and place thereon a good layer of well decayed cow manure, then a layer of good soil, and another layer of manure, adding a good sprinkling of bone meal and burnt soil. Make all firm by ramming. By the beginning of February the plants should be ready to plant out; place them 10 inches to 1 foot apart, in a double row in the soil previously prepared.

A wire should be strained along the bottom of each row, and another near the glass; between these strings should be strung as for Smilax, only of a stronger nature, and the plants trained to them. Keep the temperature at 50° to 55°, without excessive fire heat; rather let the temperature fall a few degrees in bad weather. A little air should be admitted at all times through the top ventilators, unless, of course, the weather is very severe. Syringe the plants on fine mornings and water them sparingly, until they are established.

If finally grown in 10-inch pots the Sweet Peas may be potted in pairs and trained as advised for those planted out. When the plants reach the glass they may be taken down and started up again. The best method is to take down four plants at the end of the row, lay them out carefully and then train the fifth plant along so as to replace No. 1. By following all round the double row, the first four plants will eventually replace the last four plants, and it will be quite some time before the growths again reach the roof glass. *T. Baines, The Gardens, Langham Oaks, Colchester.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

JOTTINGS ON NEW OR RARE PLANTS.

THE most satisfactory Strawberry with me this year has been St. Fiacre. Planted as open ground runners last November in richly manured, sandy soil, it was the first to ripen, and we gathered a good crop. I expected it to fruit again in late September and October, as in France, but, to my surprise, it was in full bearing again on August 18. Many of the berries, which were purse-shaped or cock's-comb-shaped, measured 4 inches around, and they were of excellent flavour. I was told in France that it is most important to water the plants well in July and August.

A bright crimson Scabious from Roumania promises to make a reliable border plant, for it flowers from June onwards, and was covered with blossoms late in September. It grows to a height of 2½ to 3 feet, and is perennial; it also seeds freely. The flowers are three times the size of the Scabious sent to me by M. Correvon (said to be the red Scabious of Central Europe), and their colour is better—in fact, quite another shade, and much more vivid. I am planting some in rough grass, which is the way it grows in its native land, where the hayfields are truly a lovely sight with it in full flower. Mr. Barr thinks it may not be a true perennial, but would an annual flourish in the hay, which is cut very early and quickly in Roumania, with the Scabious in full bloom and before the seed forms?

This summer I have flowered a very unusual Foxglove, with bells of a heavy yellow and brown colour, with a little orange in it. The bells are not only along the stalk, but there are numerous side branches below, covered with bloom. The leaves are long and linear, of a smooth dark green, and rather rigid. In dark brown pottery vases the decorative effect was extremely good in the house. This came in response to my demand for Digitalis laevigata, which I had seen in the Roumanian woods. D. laevigata, however, has some purple on its creamy yellow bells, and is much lighter and more graceful of habit—indeed, rather resembling an Orchid.

Some seed picked by me in the Carpathians, of Campanula, has turned out to be C. carpatica, but with white flowers dashed with faint mauve, and quite pretty, while another proved to be C. Medium, single, and of a most curious branching habit, so that, when in bloom, it covered quite a big patch of ground. It grows quite low, and has most attractive flowers of a bright mauve colour.

A bright pink, splashed crimson, Convolvulus, the seed of which I gathered in Greece, has flowered again this year, evidently from self-sown seed; while an Ipomaea gathered by a friend in Uganda last year while walking through the tsetse-fly district, and given to me, and said to be a lovely pale blue, presumably rubro-coerulea, has behaved in the most extraordinary manner. Raised in heat, I planted the seedlings in Rose beds, which treatment suits rubro-coerulea very well. It has completely "taken charge" and proved a veritable Jack's Bean-stalk, for it has grown rampantly everywhere and over everything, but without the sign of a flower. Plants in a stove house and in a cool house have not flowered either. Can it be that this is a perennial climber that requires two years to make its growth? I shall try the inside plant again next year, but those out-of-doors will succumb in the winter.

I have just returned from the Pyrenees, where the most interesting thing in the gardens was Lagerstroemia indica. This shrub, grown as standards, bushes, or small trees, makes the most extraordinary impression on one. There is not much flower in gardens, so far south, at the beginning of September, beyond Bignonias and Althaeas, so that the sight of the resplendent blaze of colour of the Lagerstroemia comes quite as a surprise. This is generally of the most vivid rose pink imaginable—more metallic, even, than Dorothy Perkins Rose. Instead of falling downwards the panicles of bloom stand up like those of the Horse Chestnut, which it somewhat resembles, and one sees no leaves at all—such is the quantity of bloom. The petals are like the daintiest crinkled silk, and it is called the Crepe Flower in the Southern States of America. It is also in mauve and in pale pink, and one tree, 25 feet high, in a hotel garden at Salies de Béaus, was (next to a Jacaranda) the most lovely thing I have ever seen. It had two or three pale grey stems, and above them clouds of mauve—the leaves like large Privet leaves. Would it be possible to grow it here in tubs, I wonder, in a cool house or even a coach-house in winter (for there is often frost in the Pyrenees), standing it outside in summer like an Oleander? Or is there not sufficient heat in our sun to ripen its wood? Perhaps some readers of *Gard. Chron.* may have grown it years ago, when conservatories existed. Nearly every farm had one in its bit of garden, as well as all the private gardens. *Alice M. Martineau.*

GARDEN NOTES FROM S.W. SCOTLAND.

THE effect of autumnal colour in dying foliage is usually left to chance; there must be few places where, as in Sir George Holford's grounds at Westonbirt, trees and shrubs have been planted with specific intention to secure and enhance it. But nature is generous and does not rely upon human design to kindle the fleeting glories of October. Fleeting they must be on each individual plant; but there is a long succession of change, especially after such a streaming August and September as we have had in western Scotland. At present, in mid-October, three plants outbid all others in brilliant raiment. The first is a forest tree—Cercidiphyllum japonicum, whereof the clear carmine and gold sprays tell with exquisite effect beside the silver-grey of Eucalyptus coccifera (I think that is the species). The next is a shrub, the Swamp Blueberry—Vaccineum corymbosum—which does not ask for a swamp in our humid atmosphere, indeed rather resents it, preferring sound land, where it clothes itself at this season with vermilion more intense and more uniform than anything else we have here. Lastly comes a herb which came to me years ago from Glasnevin, and has outlived its label. I believe it is Rodgersia aesculifolia rosea; it has pink flowers and its leaves are now rich, soft crimson, a joy to behold. Presently the Azaleas will vie with these in brilliancy, and already Funkia Sieboldii shines as a long, bright yellow margin to a carriage drive. The blue flowers of Aconitum 'Wilsonii provide a cool relief to all this fiery colour, and may be relied on for a profusion of blossom when all others of the genus, except the rather dingy climbing A. Vilmorinianum, have gone to seed.

Through summer and autumn we have been waging unremitting war in the borders against Polygonum polystachyum, which in an evil hour was admitted to the flower garden many years ago. The slightest relaxation of discipline would entail hopeless confusion, forasmuch as there is hardly any limit to the distance to which this Indian mountaineer will send its runners or to the depth at which it will plunge its roots. But in woodland it is priceless at this season, when it fills a glade with drifts of white flowers like fine lace-work and the air with far-flung fragrance. P. campanulatum, a Chinese newcomer, belongs to the same group of this most Protean genus, but is not so irrepressible, for although it spreads pretty freely, it does so above ground and may be kept in check. Although it begins opening its pink and white flowers in July, a couple of months earlier than P. polystachyum, it is still in full bloom now (October 16), and will continue until nipped by the first frost. It is a thoroughly desirable plant. P. cuspidatum is as uncontrollably rampant as P. polystachyum, without beauty of blossom to atone for it, and should not be planted anywhere, whereas P. sachalinense may be allowed to flap its great leaves, like the ears of a young elephant, in some corner of the demesne whence it cannot gain access to lawn or border.

Those who enrich (or dilute) garden craft with a smattering of botany may find pleasure in the contrast between these giant Knotweeds and the lowly, close-trailing P. vaccinifolium, now covered with bright pink spikes of flower of Heath-like semblance, and a further contrast is furnished by the climbing type—P. baldschuanicum and Aubertii, which run up a wall or sparely branched tree to a height of fifteen feet or more. There is some property in all species of Polygonum that renders them unpalatable or poisonous to the all but omnivorous rabbit; they may therefore be planted in woodland—the proper place for the robust kinds.

Influence of the cold, wet summer of 1922 is still apparent in several plants, notably in Arum italicum, which it is good to allow a free run in some spare corner of the flower garden. This time last year such a corner was brilliant with scores of closely clustered spikes of scarlet berries, this year there is not one, and whereas the summer and autumn of 1923 have been, in Scotland, as cold as those of 1922, and even wetter, one cannot expect the Italian Arum to make much of a display in 1924. Last year Buddleia, Sedum spectabile and Asters were peopled by dozens of Red Admiral butterflies, with a sprinkling of Painted Ladies—this autumn I have seen but one of the former and none of the latter. *Herbert Maxwell, Monreith.*

PLANT NOTE.

CERCIDIPHYLLUM JAPONICUM.

IN reply to the note by Sir Herbert Maxwell on Cercidiphyllum japonicum in *Gard. Chron.*, October 13, p. 224, I believe it is regarded as a tree in Japan, and the specimen he refers to must be a very fine one. Here we have several specimens growing as bushes, and, although they were planted in good soil about eight years ago, they are still only about five feet high, and the same through. The colouring of the foliage is, just now, most delicate and beautiful, but the tones will deepen as autumn wears on, and later, through the winter, the fine twiggy wood will be most attractive. I should be interested to know if there are any large trees of this plant in this country. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

THE ROSE GARDEN.

ROSE LEONIE LAMESCH.

This polyantha variety appears to be falling into neglect and may be little known to those who have recently taken up Rose growing. It is hardly an exaggeration to say that Léonie Lamesch is unique in colour, form and perfume. Polyantha pompons are, as a class, deficient in fragrance. Such commonly grown varieties as Orleans, Jessie and Mrs. Cutbush are scentless; likewise those two varieties, with perfect miniature blooms, Cecile Brunner and Perle d'Or. But the subject of this note is strongly perfumed, with an odour all its own, suggestive of Sweet Briar and fresh Apples.

The colouring of Léonie Lamesch is just the kind to blend well with the Pernetiana reds and yellows, should a pompon be wanted as an addition to beds composed of this type of Rose. The flower is fully double, of a deep orange red with a golden centre, and about the whole there is a gleam of copper. The flower buds are peculiar in that they have a truncate, crumpled, unpromising appearance; yet they unfold into very pleasing miniature, cup-shaped blossoms of unusual hues.

Polyantha pompons may be conveniently divided into two groups, viz. (1) those which produce large clusters of bloom, like Jessie, Orleans, its desirable sport, Coral Cluster, and Nurse Cavell, all of the latest and best; and (2) those which give only few-flowered sprays, like Cecil Brunner and Perle d'Or, already mentioned. Léonie Lamesch belongs to the latter group, with usually five to seven flowers to a spray. This paucity of flowers in a cluster may be considered a drawback from the bedding standpoint. But Léonie carries its flowers erect, whereas some of the other group of polyanthas are apt to have their trusses of bloom top heavy, so as to need artificial support. It is a free bloomer in the sense that one set of flowering shoots is soon followed by another.

Léonie Lamesch is a useful Rose to cut for indoor purposes, as its buds, if not too tightly closed, continue their expansion in water, so that a bowl of this variety may be relied upon to look well for a week, provided care is taken to remove the individual flowers as their colour fades. It blooms particularly well in the autumn.

It is a great advantage to have free flowering varieties of such rich tints at this season of the year, as they harmonise better with the changing foliage around than do pinks, whites and pale shades generally. These are more in keeping with summer with their suggestion of coolness.

Léonie Lamesch cannot, unfortunately, be given the credit of withstanding rain well. This, I am inclined to think, is its chief defect. The advanced flower buds are apt to rot and go messy during a spell of wet weather. Against mildew and black spot it appears fairly well proof; but green fly shows rather a preference for it.

Little need be said about its foliage, except that one can fairly well recognise the variety from its leaf alone. For a polyantha Léonie Lamesch is a strong grower, and should a bed be devoted to it and a low grower wanted for the outside, then the most fitting companion would be the other Lamesch, Eugénie. This is quite a dwarf variety, and much paler in hue. It is said to have a distinct odour of Violets, though I cannot say that I have detected it.

Both varieties, Léonie Lamesch and Eugénie Lamesch, were brought out by Lambert in 1899. In the former, at any rate, judging by its colour and scent, one imagines there must be some Austrian Briar in its parentage. *J. P. Carlisle.*

FIG. 91. ROSE PHYLLIS BIDE: A NEW ROSE-PINK POLYANTHA VARIETY. NATIONAL ROSE SOCIETY'S CERTIFICATE OF MERIT, SEPTEMBER 20, 1923 (SEE P. 191).

HARDY FLOWER BORDER.

CHRYSANTHEMUM (PYRETHRUM) ULIGINOSUM.

Although its value is considerably depreciated by the rise of the early-flowering Chrysanthemum and the development of that grand plant, the old Chrysanthemum or Pyrethrum uliginosum ought not to be quite neglected, as it is able to withstand more severe frosts without having its flowers disfigured. Then it is of considerable value in the back row of the border, where its stature renders it conspicuous and its blooms are very welcome, and afford good material for cutting late in the season. In the wild garden, also, it is serviceable in big clumps and mas and, when grown in quantity, will often supplement the supply of cut flowers at a time when such material becomes scarce in the open garden. Associated with the perennial Asters, or Starworts, it is of high worth indeed. The wonder is that no one seems to have done anything towards improving it, whereas with the C. maximum varieties there have been very considerable advances within a few years. Surely C. uliginosum would give useful varieties if some attention were paid to raising and selecting seedlings with a view to continued work on the same lines.

It seems almost unnecessary to give any description of this fine old perennial. It grows from five to even nine feet high, but if in dry soil it is liable to lose some of its lower leaves. It has good foliage, and a wealth of white flowers with a greenish centre—much more pleasing than the term "greenish" would convey. It may be planted in spring or early summer. *S. Arnott.*

THE BULB GARDEN.

DARWIN TULIPS.

(*Concluded from page* 237.)

Other Good Varieties.

Andromaque. A very distinct variety; large flowers of a bright garnet-red, white base; a stately plant; 29 inches.

Psyche: A very large flower with long petals, colour rose, silvery inside, pale blue base; 27 inches.

Afterglow: A large globular flower, rose-shaded amber, edges of petals deep amber; a very remarkable flower when seen at its best, but not every bulb produces a good flower.

The following is a list of varieties I have grown and discarded either from some weakness or on the too-much-alike principle:—Antony Roozen, a good, large flower, but with a cold look; Baronne de la Tonnaye, too much like Edmée; Centenaire—did not like the colour; Dal Ongaro, sends up too many flowers with deformed petals; Donders, too small—Andrea Doria is far better; Dream, a pretty flower, but very weak in the stalk and takes the "fire" badly; Edouard André, a large flower, but not a pleasing colour; Isis, too much like Feu Brilliant.

Madame Krelage is not distinct enough from Edmée; Moralis, a very fine flower at its best, but it is necessary to have a 20-yard bed to enable one to cut a good show bunch; Nora Ware, too small a flower; Princess Juliana, not quite distinct enough from several other cherry-reds; Remembrance, too dull and funereal-looking; Sophrosyne, not distinct enough; Van Poortvliet, a pretty flower, but the plant is very given to "fire"; The Sultan, too small and not a very good doer; Whistler, a very fine flower, but with us would always "break" into nasty streaky blooms; Yolande (Duchess of Westminster), a lovely flower, but a bad laster and a weak plant—Clara Butt and Julie Vinot are far better; Gipsy Queen, quite a good purple maroon, but not equal to Leonardo da Vinci.

It is quite certain that really good flowers and really good bulbs will not be obtained from bulbs planted in poor soil. At the same time I do not think that any bulb likes fresh manure. In growing Darwins by the acre we manure heavily the year before, giving from 20 tons to 40 tons per acre of good stable or cow manure as a dressing; then grow a crop of Potatos—early sorts for choice. After the Potatos are lifted, the land is ploughed and harrowed, ready for planting the Tulips in October. This ensures a clean bed for the bulbs and soil which has been well broken up. This method is, of course, only applicable to cultivation on a large scale, but amateurs may learn something from the methods of professional growers, even if they do not follow them exactly.

I have heard Hop manure highly spoken of, to be dug in before planting the bulbs, but have not tried it. What I have successfully tried, when there was a doubt about the soil not being rich enough, was a light dressing of peat moss stable manure spread on the surface during the winter—say, an even covering of half an inch. This "mulch" is very beneficial and is not unsightly.

Darwin Tulips may either be planted in beds, some 5 inches apart, to form a massive display, or placed between such plants as Myosotis, double Arabis, Violas, or any other suitable covering plants; or they may be planted in clumps of from six to twenty bulbs in the herbaceous border. The partial shade of fruit trees or other deciduous trees is very favourable to the Tulips, as it enables the blooms to last nearly twice as long as they do in the full sunshine.

Unfortunately the ground in such positions as these is apt to be poor, so the site chosen should be well prepared. It is a good plan to take out a hole the right size for the group to be planted, about 4 inches deep; dig in some manure or Hop manure, place the bulbs in position—avoiding a too formal grouping—and then replace the top soil. Or leave out the manure, but stir up the soil at the bottom of the hole, plant the bulbs, and give a top dressing of stable manure after planting.

On strong soil I consider 2½ inches of soil above the bulb to be sufficient; on light, dry soils, deeper planting may be better. Planting should not be done too early, or the growth will come up in the very early spring, and is very likely to become injured by frost or hailstorms. I have had a fine crop of late Tulips entirely ruined by a twenty-minute hailstorm.

Mr. Jacob and some other writers recommend November (about Lord Mayor's Day) as the correct time for planting. This may be right for the amateur, but, where hundreds of thousands have to be dealt with, this date is too late. The land may be in good order when one starts operations, but it is sure to get wet, cold, and sticky before the work is finished.

I think it is more important to put bulbs of Darwin Tulips into a comfortable soil-bed a little early than to put them into an uncomfortable one at what is considered the correct time. So I would name the second week in October as a good all-round time for planting.

In the spring, weeds must be kept down, but this must be done with great care, for, if the foliage, which is very easily cracked and broken, be injured, attacks of the dreaded "fire" are very likely to follow, with disastrous results. This "fire" is a fungous disease following any damage to the foliage, either by frost, hail, or sometimes by sea fog. If the plants escape this plague, and decent weather occurs at flowering time, a glorious display may be looked for in the month of May, well repaying the outlay on bulbs and the work of planting and weeding. A small Dutch hoe (4-inch) is the best tool to use among bulbs. A careful worker can push it under the foliage of the plants, without doing any damage, and the stirring of the soil is of great benefit, apart from killing the weeds; caked or cracked soil is never good for growing plants.

Certain growers leave their Darwin and other May-flowering Tulips in the ground for two or even three years, but I can state from long experience that on our soil in Nottinghamshire this practice does not pay. The plants will flower the second year, but never so well as the first, and the third year half them will have disappeared, and the remainder will be but ghosts of their former selves. The Tulip comes from a warmer climate than ours, and, no doubt, gets a summer baking, which ripens the bulbs thoroughly and enables them to withstand their natural enemies. Under our cooler conditions it requires annual lifting and artificial ripening to ensure success.

As soon as the foliage has turned yellow or brown and the sap has returned to the bulb, and before it has become dead and brittle, is the time to lift the bulbs. If left too long, the tops break off during the process of lifting, and then it is often difficult to find the bulbs. We begin lifting about the end of June or the beginning of July.

All varieties of Darwin Tulips will not be ready at the same time, so it is best to commence with the earliest-ripening ones first, and follow on as they become ready. Remove the tops and as much soil as possible, and place the bulbs in shallow boxes or trays, and remove them at once to a shed or room, and keep them fairly warm and free from strong draughts, or all the new skins will split. As soon as the bulbs are dry, they should be cleaned, divided, and sorted into sizes, reserving the full-sized bulbs for planting, and either throwing away the offsets or at planting time putting them closely together in a nursery bed to grow into flowering bulbs for another season.

If lifting be done at the right time, and proper care be taken of the bulbs after lifting, there is no reason why the amateur should not have good bulbs for many years.

I venture to add that the above notes on planting and lifting, etc., will apply equally well to all other late-flowering varieties as to Darwin Tulips. *J. Duncan Pearson, Lowdham, Nottinghamshire.*

DEVELOPMENT OF THE DAHLIA.*

(*Continued from page* 238.)

In a later period the bi-coloured varieties were preferred in some places, and such flowers, ordinarily white with coloured edges, were grouped under a separate name, i.e., Dahlia Parisiens, in France. One of the best known of the more recent varieties which is much appreciated in Holland is the dwarf growing Helvetia, which was sent out by the Swiss originator, together with another variety of the same character named Soleurois; the latter seems to have been lost.

Apart from such exceptions to the rule, the single Dahlias as a class have never gained general popularity. With all other Dahlias of their period they had to give up their position in favour of the Cactus Dahlia.

The Cactus Dahlias.

An occurrence which should later prove to have entirely altered the line of the production of new varieties occurred in 1872. It was then that a Dutch nurseryman, Mr. van den Berg, of Jutfaas, received with other plants some Dahlia tubers from Mexico. Although they were in very bad condition, he succeeded in flowering them, and he found that they produced brilliant coral-red flower heads with pointed florets, quite a new type, which he did not know. The Dahlia was offered in Mr. van den Berg's catalogue as D. Yuarezi, a name suggested by Mr. R. C. Affourtit, of Dahlia fame.

The newcomer, however, did not attract any special attention. Tubers were sold to a French firm, but no one in France cared for it; from France it came into the hands of an Overveen bulb firm with no other result, and only after it travelled from Overveen to England, where it at last reached the late firm of Henry Cannell, it received the appreciation and the honour it deserved. Shown at a meeting of the Royal Horticultural Society in September, 1879, it created a sensation. Figures of it appeared in the leading British horticultural papers, and the nurserymen soon found that it better suited the taste of the public than the declining, old-fashioned show Dahlia. Hence the raising of seedlings was led in a new direction, and raisers tried to obtain more varieties with pointed petals. At the same time, old varieties which did not possess the qualities of a good old Show Dahlia, and had more or less pointed petals, were carefully preserved and multiplied. So the old white Ariel, the bi-coloured picta formosissima, soon joined D. Yuarezi as the first varieties of a series which has later received the collective name of Cactus Dahlias.

The rise of the Cactus Dahlias dates from about the year 1890. The considerable number of new seedlings yearly exhibited at autumn exhibitions showed a remarkably steady improvement. I very well remember the surprise caused by the champions of 1894: Matchless, Gloriosa and Lady Penzance, that were of quite novel appearance. The improvement continued in such a degree that varieties more than three years old were not seen on show stands, as they would have been beaten by newcomers. As a contrast it may be remembered that some of the leading old-fashioned Show Dahlias kept their position for twenty to thirty years.

The Cactus type, from a round flower-head with pointed florets, became more and more narrow petalled. The appearance of the flower became entirely changed, and the older varieties, which still had a certain advantage for garden use, were, later, distinguished as "decorative" Dahlias.

British growers have long held the monopoly of raising Cactus Dahlias, and the horticultural world owes to them many remarkable varieties. Several growers in Germany, France, Belgium and Italy later also obtained excellent results, but notwithstanding the serious effort to raise Cactus Dahlias with long and wiry flower stems, the large proportion of the varie-

*A paper read by Mr. Ernst H. Krelage before the International Horticultural Congress at Amsterdam, on September 18.

Digitized by Google

ties annually offered to the public had the drawback of hiding their flowers beneath the foliage. The most wonderful exhibition flowers were disappointing when planted in the amateur's garden, and consequently the strain, which in its period of glory had almost completely outshone the old ball-shaped Dahlias, began to decline when a new group made its appearance that better suited the garden demands. I refer to the Paeony Dahlias, whose sun began to rise twenty years ago.

Various Minor Classes of Dahlias.

I have still to say a few words of certain groups that appeared and disappeared in the period of the Cactus Dahlias. The success of the latter evidently was responsible for the introduction of the single Cactus Dahlias, a strain with elegant flowers, raised by an English amateur grower, Mr. E. J. Lowe, and offered by the firm of Cannell thirty years ago.

About the same time another gentleman grower, Mr. Girdlestone, raised a strain of very dwarf, small-flowered, single Dahlias, which were introduced under the name of Tom Thumb Dahlias by Messrs. J. Cheal and Sons, and highly recommended for beds and borders. The more recent Dutch strain of Mignon Dahlias raised by Mr. Dominicus, of Schiedam, is of somewhat similar character, the flowers being rather larger, and seems to have successfully replaced the forgotten Tom Thumbs.

Of the same age as the single Cactus and the Tom Thumb Dahlias is a double Dahlia of quite a distinct type which came from France under the name of Grand duc Alexis. It was raised by Mons. Coutant, and produced enormous flowers of a pale lilac colour, in form more or less intermediate between an old ball-shaped and a decorative variety.

In 1895, and later, some growers offered what they called Miniature or Pompon Cactus Dahlias, a name which very well suggests the character of the flower.

All these examples prove that the variability of the Dahlia had enormously increased, and although these strains could not all keep their place, they have doubtless exercised their influence on the further development of the Dahlia.

(To be concluded.)

LATE FLOWERING SHRUBS.

By far the greater number of shrubs have their season of flowering in the early months of the year, and the planter has ample material to choose from when planting for a display from March to midsummer. For a display after this period the choice of subjects becomes much more limited, nevertheless there are many beautiful shrubs which flower from July onwards and, as the time of planting is near, the consideration of a few of those which are well worth growing may be of use to intending planters.

Buddleia globosa is a deciduous shrub from Chile, reaching a height of 10 feet or 12 feet. It has long, hoary, Willow-like leaves and orange-coloured flowers borne in large, terminal, globular clusters about midsummer and extending into July.

B. variabilis is a Chinese species about 10 feet high with long racemes of lilac flowers which are very effective in late summer.

Caesalpinia japonica is an interesting shrub with rambling, flexible shoots and red prickles. The leaves are long and of a pleasing green; the flowers, which are borne in racemes in July, are a bright canary yellow against which the reddish anthers show conspicuously. This shrub should be planted where it has plenty of room to develop.

Calycanthus occidentalis is a much-branched, large-growing, North American shrub well worth growing for its highly fragrant and brightly coloured flowers. It should be given an open sunny position to favour free flowering.

Ceanothus americanus, a dwarf shrub bearing terminal clusters of white flowers in summer, is quite hardy and may be planted in the front of the shrubbery. C. azureus is a much more beautiful species, but not quite so hardy and should be given a sheltered position; it is a delightful subject for training against a wall. There are several good garden varieties, amongst which may be mentioned Gloire de Versailles (blue), Marie Simon (pink) and Indigo (dark blue).

Clethra alnifolia and allied species are North American shrubs, the flowering period of which extends from July to October, and as the number of flowering shrubs which bloom during this period is very limited, they are most valuable. They form loose bushes 6 feet to 8 feet high and bear erect racemes of white, bell-shaped, very fragrant flowers in profusion. They delight in a moist, peaty soil in which the majority of the so-called American plants flourish.

Cytisus austriacus is of value because its effective yellow flowers are borne in abundance in July; C. nigricans, another Austrian late-flowering Broom, should be grown in every garden. Its branches are smothered with bright yellow flowers in July and August and the plant remains a long time in beauty. Both these Brooms do well in open, sunny positions and in poor soil.

Deutzia crenata and its double variety are handsome Japanese shrubs which commence to flower about midsummer and continue into July, when the majority of the shrubs of this section have passed.

Escallonia macrantha is a South American evergreen shrub with rich, glossy leaves and bright, Fuchsia-like flowers. It is perfectly hardy in the south and is worth the protection of a wall in the Midlands and north.

Fuchsia Riccartonii, of garden origin, has the reputation of being the hardiest of the Fuchsias and is an excellent plant for summer and autumn floral display. It frequently makes a shrub of fairly large dimensions in the south.

F. gracilis is a slender and beautiful species and appears to be equally hardy. Genista aethnensis, a native of Sicily, is not common in gardens, yet it flowers in July when flowering shrubs are none too plentiful. Its long, slender branches produce rich golden-yellow flowers in abundance, and it would be difficult to find a shrub better suited to a hot, dry soil. G. virgata flowers a little earlier, but extends its flowering period into July. It is probably the most beautiful of the taller Brooms and frequently reaches a height of 15 feet. It flowers sparsely in the young state, but older specimens are a glorious sight, every twig of the somewhat straggling branches being covered with flowers in their season.

Hamamelis virginica, a species with Hazel-like leaves, is a sturdy North American shrub and the only autumn-flowering species of the genus. It has the narrow, twisted, bright yellow petals characteristic of all the Hamamelis flowers, and the blossoms are produced in dense clusters.

Hibiscus syriacus is an upright-growing, deciduous shrub about 6 feet high and particularly valuable, because it flowers at the end of August, when few other shrubs are in flower. It thrives in well-drained, loamy soil in a position fully exposed to the sun. There are several good garden varieties, ranging in colour from white to purple, both single and double forms being represented.

Hydrangea paniculata and its variety grandiflora are invaluable autumn-flowering shrubs from Japan. The huge, pyramidal-shaped heads are composed entirely of sterile blossoms. Both may be grown as bushes or standards, but in any case the plants should be pruned hard when they are dormant.

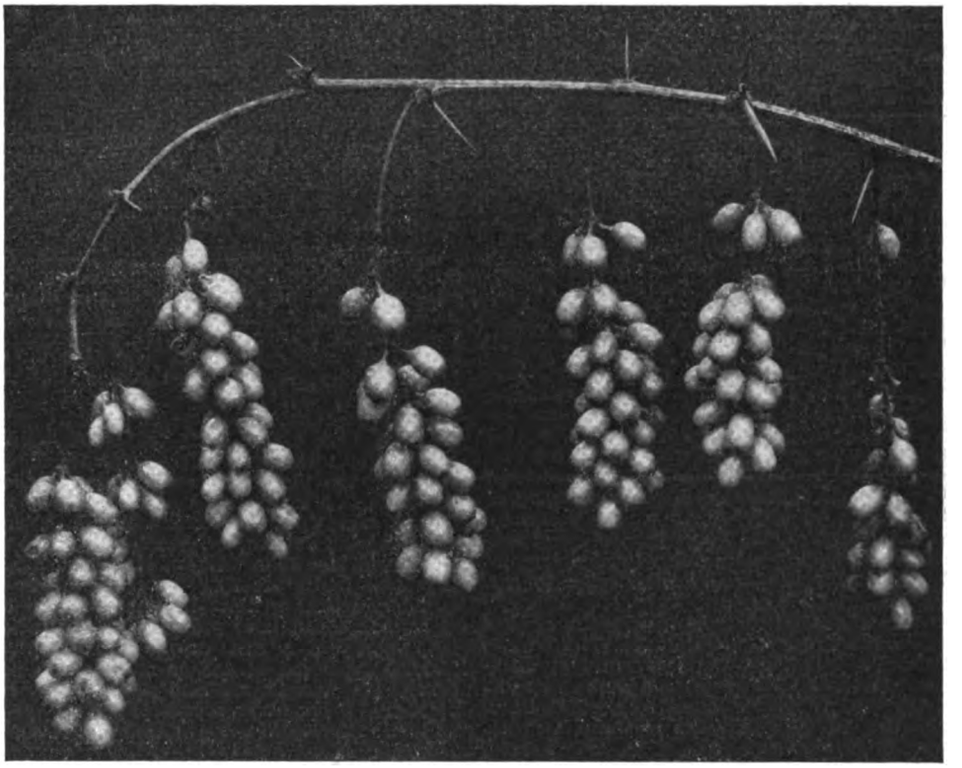

FIG. 92.—FRUITING SPRAY OF BERBERIS BRACHYPODA VAR. GIBBSII: R.H.S. AWARD OF MERIT, OCTOBER 6, 1923 (SEE P. 239).

Hypericum aureum is a North American shrub attaining a height of 4 feet, and very valuable for the front of the shrubbery. Its orange-yellow flowers, produced in August, are about 1½ inches across and have a large and conspicuous mass of stamens in the centre which makes them very showy. Several other Hypericums are well worth growing, not the least valuable being H. calycinum, an attractive plant forming a dense mass a foot or so high and very suitable for covering bare places on banks or under trees.

Ligustrum lucidum has large, glossy, handsome leaves and is the most ornamental of all the Privets. It reaches a height of 10 feet to 12 feet and has large panicles of white flowers in July and August. L. Quihoui is still later, producing its terminal panicles of flower in late September, and for this reason alone is worth growing.

Olearia Haastii is a valuable, evergreen, Box-like shrub from New Zealand. It is compact and slow-growing, and its branches are laden

Digitized by Google

with small, Daisy-like flowers in July and August. O. dentata has large, Holly-like leaves but is not so hardy as O. Haastii and needs the protection of a wall. Spiraea ariaefolia is a well-known North American shrub reaching a height of 10 to 12 feet. The leaves are dark green above and silvery beneath; the plume-like clusters of creamy-white flowers are produced in abundance. S. Douglasi forms a crowded bush of erect shoots 6 feet or 7 feet high, every shoot being terminated by a dense spike of rose-coloured flowers in August. S. japonica and its varieties are handsome, dwarf shrubs, bearing larger flat corymbs of rosy flowers, and are amongst the most useful of summer and autumn-flowering shrubs. *W. Auton, Pyrford Court Gardens, Woking.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Red-plant Disease in Strawberries.—My attention has been directed to an article in the current issue of the *Journal of Pomology* by Messrs. Peren and Ballad, of Long Ashton. In this article the joint authors point out that eelworms (Aphelenchus fragarieae) *can always* be found in the growing point of "Red-plants." This is a most remarkable statement in view of the previous and equally emphatic statement sent out by Long Ashton that parasitic eelworms *could not* be found in affected plants.

In my own reports to the officials of the Ministry of Agriculture I have repeatedly pointed out that the eelworms were to be found in the very spot where the joint authors now claim to find them. Perhaps the most interesting point about the article, having regard to the correspondence which has taken place in the pages of the *Gardeners' Chronicle*, is the following statement: "We wish to extend our thanks to Dr. T. Goodey, of the London School of Tropical Medicine, for identifying eelworm material sent to him." One can only assume from this that had I sent my eelworm specimens to the same authority, instead of attempting to get the Ministry's pathologists to agree to my point of view, the *accepted* date of the discovery of the organism producing the disease would have been 1920 instead of 1923. The article in question contains nothing that is new to those who have studied the disease, and the "small leaf" phase which led Captain Wellington to his theory of reversion is well known to growers as a form of the "Red-plant or patch disease" which I have consistently maintained since April, 1920, was due to eelworm and which the Long Ashton authorities attributed to mosaic. In view of this *volte face* it is not surprising to read that Messrs. Ballad and Peren consider that further correspondence is unnecessary (p. 149). I may add that the disease is even more general than the authors imagine, but that where first-class cultivation is carried out, with proper attention to such details as the selection of runners, rotation of crops, and manuring of ground, there is but little to complain of. *W. H. Johns, Town Hall, Bermondsey.*

Holland Park Hall Show.—There is a small error in your report of the R.H.S. Show at Holland Park Hall. Your reporter states that there was only one entry in the County Class, comprising Somerset, Devon, Dorset, Cornwall, and Wilts; yet there was one other—myself. In your issue of October 13 you try to account for the comparatively small number of entries in the fruit classes, and suggest that the small amount of prize money is one of the causes. Doubtless that is true up to a certain point, but there are other reasons. Is the general management satisfactory? Is it not time that new and younger men were engaged to carry out the judging—men who are now in harness? I have no hesitation in saying, as a competitor for many years, that complaints are louder and longer in this respect each year. Another cause, and probably the principal one—why fruit growers do not like the Holland Park Hall Show is that the exhibits are placed in the gallery, and the fruit exhibits are scattered all around the long, narrow space, which makes it very difficult to supervise the exhibits, consequently many of the dishes of fruit are stolen. My first prize dish of Cox's Orange Pippin Apple was taken early on the Thursday morning. We fruit growers feel we are consigned to the background, being, so to speak, last on the list, and we long to return to the hall at Westminster. *J. A. Stidston, Bishop's Teignton, South Devon.*

—— —— In your editorial comments on the recent exhibition at Holland Park Hall (see p. 213) you very rightly refer to the great falling-off in quantity and quality of the fruit exhibits staged, as compared with the shows one recollects in days gone by. Granted this has been a bad season for hardy fruit, nevertheless the exhibits were not worthy of the R.H.S. You comment on the fact that the County Class for Kent was an absolute failure; this was once a very popular class, and splendid fruit used to be staged in it. I believe there is a rule that, if a grower sells any fruit from his garden, he is considered to be a commercial grower, and is thus debarred from this show. Many of the best growers in Kent do sell surplus fruit, and a few years ago several of these were informed that, owing to this fact, their entries could not again be received. I venture to believe the fruit show has never been the same since that time. *B. J. Mercer, Chart Sutton, Kent.*

Dr. Hogg.—Mr. Brotherston's historical notes on page 218 are exceedingly interesting to a student in old London nurseries and kindred establishments. His remarks respecting Dr. Hogg, whom I knew quite well, induce me to add a personal note about him. He was a burly gentleman—a great snuff-taker. It was to him and Mr. Monro, grandfather of the present proprietors of the great Covent Garden business, that I first came to London, and I had to decide whether I would enter the market trade or the plant and seed trade. I chose the latter. I remember Dr. Hogg asking the firm I was with to recommend him a sub-editor for the *Journal of Horticulture*, and we mentioned Mr. John Wright, then gardener to the Hon. Leslie Melville in Lincolnshire—a sound, practical writer. He was evidently the right man, as in later years he became editor. Dr. Hogg died a rich man, leaving about £80,000 made out of one or other of his ventures. Mr. Wright has also passed away, full of years, leaving three sons, all well known in the horticultural world. *Donald McDonald, Hatton Garden.*

General Oglethorpe.—As success has followed the excavations made in the church at Cranham, Essex, by Dr. Jacobs, president of the Oglethorpe University, for the body of General Oglethorpe, the founder of the State of Georgia, U.S.A., increased interest is attached to a printed document in my possession, bearing the title: "*A Sermon Preach'd before the Trustees for Establishing the Colony of Georgia in America. And before the Associates of the late Rev. Dr. Thomas Bray for Converting the Negroes in the British Plantations, and for other good Purposes. In the Parish Church of St. Mary-le-Bow. March 15th*, 1732." This sermon occupies the first 32 pages, and is followed by 18 more, comprising "The General Account of all Monies and Effects received and expended by the Trustees." For encouraging and improving Botany and Agriculture in Georgia, the donations mentioned are from Sir Hans Sloane, Bart., £20; His Grace the Duke of Richmond, by the hands of Mr. Robert Sedgwick, £30; the Rt. Hon. James Earl of Derby, by the hands of Mr. Barnard Frederick, £50; Charles Du Bois, Esq., £10 10s.; James Oglethorpe, Esq., by the hands of Mr. Peter Simond, £5. Of this total of £115 10s., £75 was, on October 4, 1732, given to Mr. William Houston, for half a year's salary, advanced to enable him to proceed on his voyage to collect plants, etc. For use in the trustees' office, James Oglethorpe contributed a large African Mahogany table. *Gurney Wilson, Haywards Heath.*

A Fine Crop of Arran Comrade Potatos.—I enclose a photograph [not suitable for reproduction.—Eds.] of a crop of Potatos I have lifted this autumn, which I think almost constitutes a record. I planted one hundredweight of seed of the variety Arran Comrade on seven poles of ground, and I lifted 18½ cwt. of good sound tubers. *T. S. Lewendon, The Gardens, Hoathly Hill, West Hoathly, Sussex.*

British Timber of Ancient Date.—One of the oldest existing specimens of native timber, that has been shaped by the hands of man, is the original haft of a stone axe from the Solway Moss, which was presented to the British Museum by Sir George Musgrave, Bart., in 1857. This prehistoric implement of wood and stone was discovered by a labourer at a depth of six feet, when digging peat in a bog near Longtown. The handle, which is 18 inches long, and of various thicknesses from an inch to two inches in diameter, is in a very primitive condition, a hole having been formed at the thick end of sufficient size to allow the stone axe head to pass through, and to which it is secured by means of a wooden peg. It appears to have been water-worn, and is more inclined to be flat than round. The wood is of a dark colour, resembling Bog Oak, and though much twisted and warped, and inclined to be brittle, is in an excellent state of preservation. Judging by inference, this haft of wood is of older date than either the coracle or dugout, rudely constructed boats that primitive man, by the aid of stone implements and fire, formed from the butt end of an Oak tree. Of timber that was made use of during the Roman period in this country, there are many examples, such as the piles of old London Bridge, the Roman boat found by the London County Council when excavating for the site of their new hall by the Thames side, and in the remains of a Roman bath which still exists under the Coal Exchange, near Billingsgate Market. Other existing remains of timber made use of by the Romans are to be seen in the museum at Kew, and include one of the old piles of London Bridge, taken up in 1827, and a block of Oak found below the Roman wall, when cutting the canal from Carlisle to the Solway Firth, in 1823, both of which are in a sound condition. Of timber that has been in use for from 800 to 1,000 years, there are still a few examples, as in the Tower of London, and in Greenstead Church, in Essex, which, though erected prior to the Norman Conquest, is in good condition. I have just had an opportunity of examining some of the timbers from the original wooden castle that was erected on Rayleigh Mount, in Essex, in 1096. Some of the beams, which are 18 inches through, are in a remarkable state of preservation, and, indeed, may be looked upon as the oldest and best-preserved Oak wood of which we have an accurate record. These timbers were recently found in the carpenter's shop, under ten feet of soil, and surrounded by a thick layer of bark and chips. These ancient specimens of British Oak are carefully preserved in Prittlewell Priory, near Southend-on-Sea. *A. D. Webster.*

Long-Lived Palms.—It may interest some of your readers to know that I have two Palms growing in one pot, without drainage. They have lived here in those conditions for over forty years, and are still flourishing. *Alice G. Pollock, York Terrace, Regent's Park.*

Autumn-flowering Roses.—The new Rose garden planted last November at Mrs. Finchett Maddock's home at Cae Gwyn, Carnarvon, has proved a great success, and the flowering of the plants during September has been the admiration of all who have visited the gardens. The plants are remarkably clean and healthy, and at the end of September the following varieties were in full bloom:—Christine, Mme. Abel Chatenay, K. of K., Padre, Isobel, Ophelia, Mrs. G. Shawyer, Modesty, Gorgeous, Mrs. H. Stevens, Margaret Dickson Hamill, Mrs. Wemyss Quin, Lady Hillingdon, General McArthur, Lady Pirrie, and Admiral Ward. *G., Carnarvon.*

SOCIETIES.

BRITISH MYCOLOGICAL.

The twenty-seventh annual meeting and autumn foray of the British Mycological Society was held at Windsor from September 28 to October 3. On Saturday, Virginia Water was searched. Here, as throughout the foray, the amazing abundance of Amanita mappa was remarked, the nearly related A. phalloides being extremely scarce. This has been a common experience during the present season—at least, in the south. The more noteworthy finds were Russula azurea, Pleurotus pantoleucus, Cortinarius claricolor, C. pholideus, Polyporus adiposus, Tremellodon gelatinosum, and Sparassis crispa, the burden of a specimen of the latter being shared by two members of the party.

In the evening the annual meeting was held. Mr. J. Ramsbottom was elected President for 1924. Miss G. Lister, Vice-President, and Messrs. W. J. Dowson and C. J. Sharpe to the Council.

Several parties went out on Sunday, various parts of Windsor Park being visited. Additional finds were Collybia longipes var. badius, Cortinarius dolabratus, Hebeloma longicaudum, Inocybe rhodiola, Polyporus spumeus, and Daedalea biennis. In the evening Mr. F. T. Brooks gave his paper on "Epidemic Plant Diseases." The causes and conditions under which these epidemics arise were dealt with, and the importance of weather upon their development was emphasised. The nature of the delicate balance between host, parasite, and environment which determined the establishment of a disease in an epidemic form was pointed out, and the modes of dissemination of these diseases were discussed in detail. Special reference was made to Silver Leaf Disease of fruit trees, Wart Disease of Potatos, cereal rusts, and certain tropical diseases, such as those of rubber. Whenever possible, a parallel was drawn between the nature and incidence of epidemic disease in plants and in man.

Burnham Beeches was visited on Monday. In this classical collecting ground Pleurotus lignatilis, Pholiota radicosa, Rozites caperata, Cortinarius armillatus, C. argentatus, Inocybe pyriodora, and the two beautiful species of Hydnum, H. coralloides and H. erinaceus, were secured. Professor O. V. Darbishire gave his presidential address in the evening on "Lichenology." He first sketched the position of the systematists of the last century, giving a short account of Nylander (1822-1899) as typical of the school. Most of them were violently opposed to Schwendener's theory of the dual nature of Lichens, feeling that the autonomy of the Lichen group was at stake. The old hostility has now almost gone; very few, if any, systematists are opposed to the physiological school. The present need of systematic lichenology is that Lichen groups, genera, and even species should be monographed so that the exact status of many species could be ascertained and many points of systematic and phytogeographical importance cleared up. The very great difficulty encountered at times in defining a Lichen species is in part due to the fact that the Lichen fungus, usually the predominant partner from an anatomical point of view, has jettisoned the structural traditions of its free-living parasitic or saprophytic ancestors. In the Lichen structure the fungus has to adapt itself to very stringent conditions of growth. The result is that the rock forms of two allied species will often be more like one another in structure than they are like their respective normal bark-inhabiting parent forms.

The development, structure, and growth of Lichens depend upon the amount of available water. As transpiration is a much slower process than absorption, the Lichen fungus absorbs water and stores it for the benefit of the Alga. Lichen evolution is proceeding along very definite lines from the flat crustaceous, but areolate, to foliaceous, upright foliaceous, and finally true fruticulose forms. The highest physiological differentiation is reached in such forms as Cladonia, where the stem and dorsiventral leaf are clearly separated.

The foray on Tuesday was to Brockhurst Wood and Stoke Common. The former provided Hygrophorous conicus, Pleurotus sapidus, P. revolutus, Panus torulosus; the Common many burnt-ground species, as well as Helotium luteolum and a species of Pustularia.

Mr. Carleton Rea gave a talk in the evening on the principle species found during the foray This innovation was much appreciated, as the remarks were characteristic. A communication by Sir H. C. Hawley dealt with the Fungi found in August on a blackbird's nest—fourteen species were identified, ten of them Pyrenomycetes. Mr. J. Ramsbottom read a short paper on "Mushrooms and Toadstools," which had been broadcasted a few days previously. Black Park, Langley, was to have been worked on Wednesday, but the day was so wet that very little searching could be done. However, some additional species were encountered. the chief being Pluteus cervinus var. Bullii, and P. eximius, both on sawdust, Leptonia incana, Psilocybe canobrunnea, and Coprinus picaceus.

The last paper of the meeting was an account by Mr. Ramsbottom of an unpublished monograph on Discomycetes by Mr. M. C. Cooke. The meeting was in every way a success, and many rare species were found. Most of the papers were followed by interesting discussions.

CARDIFF GARDENERS'.

At the meeting of this Association, held on October 16, Mr. H. Wilkins presided, and a very interesting and instructive lecture was given by Mr. G. Chambers, of the Monmouth Education Committee, Abergavenny, on Hardy Fruit Cultivation. Planting an orchard and the effects of transplanting on the roots and subsequent growth were points ably dealt with. Mr. Chambers brought to the notice of those present the advantages that may probably result when the pruning and manuring of fruit trees are considered together. He hinted that more might be heard of this subject in future.

Mr. G. Upham has given a silver cup to the Association to be won by the highest aggregate points awarded to exhibitors at the meeting held during the session 1923-1924. The prize given by Messrs. W Treseder for three dishes of Apples was awarded to Mr. W. Davies.

BRISTOL AND DISTRICT GARDENERS'.

The usual fortnightly meeting of this Association was held at St. John's Parish Rooms on October 11, when Mr. D. Ingles presided over a good attendance. Mr. J. Banting, the lecturer, took for his subject "Trees and Shrubs of Tortworth Court." A fine collection of choice and rare trees is grown at Tortworth. Mr. Banting gave advice as to planting, protection, etc., and he was provided with many specimens, with labels attached, which he described and then handed to the audience. Amongst the species dealt with, the more important were the Acers, Quercus, Juglans, Aesculus, Fagus, Fraxinus, Pyrus, Rhus, Tilia, Carya, and Crataegus. The lecturer also referred to the various uses to which some of the less common trees are put, and at the close of the meeting he was accorded a hearty vote of thanks.

The prizes offered for a vase of Roses were won by Messrs. Grieve, Warren, Bird, and Hessy in the order named, and for a lady's spray Mr. Middleton and Mr. Mistoe led.

INQUIRY.

RHAMNUS CATHARTICUS BERRIES.

A correspondent is anxious to obtain large quantities of the berries of the Buckthorn, Rhamnus catharticus, for medicinal purposes. If any of our readers are in a position to supply these in quantity will they please communicate with us as quickly as possible.

Obituary.

Joseph Hargate Clibran.—Mr. J. H. Clibran, founder of the firm of Clibrans, nurserymen and seedsmen, of Altrincham and Manchester, passed away on the 17th inst., in his 82nd year. It is well over half a century since he first commenced, in Altrincham, what has since become one of the largest businesses of its kind in the country. Of a quiet, retiring disposition, the late Mr. Clibran possessed extraordinary activity, and devoted himself wholeheartedly to his business, in which he displayed exceptional ability for organisation, and an unusual capacity for detail. He was not the type of man who sought or desired personal publicity, but, nevertheless, he was well known to the older generations of nurserymen. Never of robust constitution, of late years he had been in failing health. About fifteen years or so ago, he relinquished active direction of affairs, handing the business over to his son, Mr. William Robert Clibran, the present proprietor. The funeral, attended by all the surviving members of his old staff, relatives and numerous friends, took place at Bowdon Church on the 20th inst.

John Yates, M.A.—We regret to record the death at Redford, Cabrach, Banffshire, of Mr. John Yates, M.A. Born in 1832, Mr. Yates had reached the patriarchal age of 91. Originally engaged in farming work, his keenness to learn led him to Aberdeen University, where he graduated in Arts in 1861, thus having been a graduate of sixty-two years' standing. Mr. Yates was a keen botanist, and from 1880 until this year he was the honorary treasurer and secretary of the Banffshire Field Club. He was the discoverer of some of the most uncommon varieties of plants in his native county, and collaborated with Professor Craib in compiling *The Flora of Banffshire*. In recognition of his long and devoted service to the affairs of the Field Club, it was only on August 24 last that a number of representatives of the Club journeyed to Redford, a picturesque and rugged district, and made Mr. Yates the recipient of his portrait and a lounge chair, the gifts being handed over by Sheriff-Substitute More, the President of the Club. The function was a peculiarly pleasant and interesting one. Mr. Yates was unmarried.

Robert Johnston Paton.—It is with deep regret we learn of the death, on the 17th inst., of Mr. R. J. Paton, J.P., one of the directors of the firm of Messrs. Samsons, Ltd., nurserymen, florists and seedsmen, of Kilmarnock. Mr. Paton was an expert in horticultural matters, and always ready to give the benefit of his knowledge and experience to amateurs needing advice on horticultural subjects. He was also greatly interested in agricultural matters, and was for seven years President of the Kilmarnock Farmers' Society. An excellent sportsman, he nevertheless found time to take a keen interest in public affairs. Mr. Paton had not been in good health for several years, but his decease came as a very great surprise to all who knew him. The funeral was of a public character, and attended by many prominent horticulturists from the district in which Mr. Paton had lived so long, and wherein he was very highly respected.

TRADE NOTES.

After the closing of their Dublin branch for a period of sixteen months, Messrs. Alex. Dickson and Sons, Ltd., of Newtownards and Belfast, have re-opened their premises at 61, Dawson Street, Dublin, and are prepared to execute orders from that address as before. The many friends of Messrs. A. Dickson and Sons will regret to learn that their financial and material loss at Dublin has been very heavy, and that they have passed through a time of great and continuous anxiety. A brighter prospect is now in view.

Abstract Published This Month.

Supporting and Training Plants.—Patent No. 202,079.—Mr. F. Lee, of Cressey Fields, Alfreton, Derbyshire, has devised a useful system of supports for growing kitchen garden produce such as Peas, Beans, etc. It consists of two rows of vertical or inclined rods fixed to a base frame which can be staked down to the ground with the plants between the rows of rods. Inclined rods are fastened to longitudinal bars which are detachably connected to tranverse pieces. The rods may be connected together by wooden rails and braced by horizontal, transverse, and diagonal stay rods or wires. The two sets of rods may be vertical, or may meet at their upper ends. The rods may be detachably secured to the frame members in groups.

This list is specially compiled for *The Gardeners' Chronicle*, by Messrs. Rayner and Co., Registered Patent Agents, of 5, Chancery Lane, London, from whom all information relating to Patents, Trade Marks, and Designs can be obtained gratuitously.

Messrs. Rayner and Co. will obtain printed copies of the published specifications and abstract only, and forward on post free for the price of 1s. 6d. each.

ANSWERS TO CORRESPONDENTS.

Apple Infested with a Grub: *E. C.* The injury to your fruit of Cox's Orange Pippin Apple has been caused by the Codlin moth. Place grease bands around the trees now, and in spring, just before the blooms have expanded, spray the trees with arsenic of lead, and again just after the petals have dropped.

Blowflies among Fruit Crop: *H. B.* The presence of flies among fruit crops has been very marked this year, and the trouble seems to be generally distributed. The position seems to have been brought about by several contributing causes. As pointed out in your letter, wasps have been very scarce this year, and this seems to be a general condition all over the country. Most people now know that up to the end of July the wasp is responsible for the death of a very large number of insects, as up to this time they are almost entirely carnivorous. Why they were scarce it is more difficult to state. It is, however, a recognised fact that warm, moist winter conditions are very unfavourable to insects hibernating as larvae, pupae or adults (though not necessarily to eggs), and the last winter was remarkably warm and moist. Another contributing factor to the presence of flies on fruit was the extraordinary amount of bird damage. This year birds did a most exceptional amount of damage. Such Pears as were produced were severely bird pecked (as usual, close to the stalk), and Apples also suffered early and extensive damage. Tits were observed doing this damage, and possibly other small birds were also responsible. These pecked places proved attractive to flies, and to such an extent did this occur that the worker on the land was convinced that the flies had "blown" the fruit. This, however, would be directly against the usual habits of any of the flesh-blowing flies, and in view of the undoubted prior bird damage, is an unnecessary hypothesis. The presence of flies in wasp-netted vicinities is more difficult to explain. The most likely explanation is that they were brought in with manure as larvae, and bred out inside the vinery. If no manure had been brought in to the vinery it would point to the wasp netting not being effective. Probably you are in the best position to form a judgment on this point. At any rate, it is unlikely that the particular conditions acting this season will be repeated often, and therefore the situation is not such as to demand special care in the future.

Books: *T. B.* The best work on Grapes is *Vines and Vine Culture*, by the late Mr. A. Barron, and this may be obtained from our Publishing Department, price 5s. 9d. post free. *J. B.* An inexpensive work on trees of the nature you desire is *Trees and Shrubs*, by Mr. W. Dallimore, which can be obtained from Messrs. Cassell and Co., La Belle Sauvage Yard, E.C., price 1s. 3d.

Celery Unhealthy: *W. W.* Without knowing all the conditions under which the crop was grown, we suspect that your Celery plants have received an overdose of manure, solid or liquid.

Commelina and Ceratostigma: *H.* Raise the Commelina each spring, from seed. Neither of the other plants is quite hardy, and in the case of these and other plants similarly tender, a stock of young plants should be kept in reserve. They are easy to raise from cuttings. A loose straw cover will in most years preserve old plants. The Ceratostigma may be enveloped in rough straw, which is an efficient protection for shrubby plants.

Correction. — The Director of the Royal Botanic Gardens, Kew, draws attention to an error which has crept into page 195 of our issue of the 29th ult. He writes: "In an answer to a correspondent it is stated that the growth found on lawns is not a fungus, but one of the thalloid Liverworts (Hepaticae). The remainder of the answer clearly shows that the plant referred to is a Nostoc, one of the lower Algae (not Hepaticae), which not infrequently appears after rain on lawns and gravel paths, and to which the name 'shooting stars' has been applied."

The foregoing note was sent to our expert who contributed the reply on p. 195; he replied as follows:—

"If the growth found on a lawn was really Nostoc, I was misled by its condition, having never seen this Alga in a half-dried state. The clue as to its greasiness was taken from the description given by the correspondent, and this might have been regarded in a variety of ways. Spirogyra may be both black and greasy, but it certainly was not this. The organism I examined was lobed and so spongy that I never suspected Nostoc, otherwise I would have put it in water and placed it under the microscope. Unfortunately I have destroyed the material."

Evergreen Shrub for a Hedge: *G. T. F.* The best evergreen shrub for a hedge in a shady place is Aucuba japonica. If this is too robust in growth, the common Box, Buxus sempervirens, may be substituted, but the position for Box should not be dark, nor the soil dry.

Fertiliser for Chrysanthemums: *Goodmayes.* A fertiliser compounded of four parts superphosphate, two parts sulphate of ammonia, and one part sulphate of potash would be very rich, and not more than half a pound to a pound should be added to each bushel of soil for top dressing your Chrysanthemums.

Gardener's Claim for Expenses and Bonus: *J. G.* It would seem that you have been badly treated by your employer, but the difficulty appears to lie in the absence of any written agreement on the subject of expenses. If legal proceedings are taken it will be for the Judge to decide whether he believes your statement or that of the employer, if the latter should be prepared to swear that he made no promise whatever to pay the expenses in question. The same remarks apply to bonus on sales. With regard to the expenses of removal, you have no claim unless you can prove that your employer agreed to pay these, or else that your employer held out to you that he might regard the appointment as a permanent one without having any intention of keeping you beyond the end of October. This, of course, would be a most difficult matter to prove, and even the fact that it had been the practice to take a foreman only from April to October in previous years would not be sufficient evidence in your favour. You had better consult a local solicitor and endeavour to bring pressure to bear on the employer to adopt a reasonable attitude.

Names of Plants: *W. D. K.* Selaginella uncinata; you can probably obtain plants from Mr. L. R. Russell, Sheen Road Nurseries, Richmond.—*G. B.* 1, Crassula falcata; 2, Hypericum Androsaemum.—*W. S.* 1, Cedrus Libani; 2, Taxus baccata; 3 and 7, Forms of Cupressus Lewsoniana; 4, Veronica Andersonii var. variegata; 5, Forsythia suspensa; 6, Solanum jasminoides; 8, Cupressus obtusa var. densa.—*A. B. H.* The white flower is Cornus macrophylla, and the lilac one Elsholtzia Stauntoni.

Potatos with Scabby Skins: *J. B.* The scabbing of your Potato tubers is only superficial and will not affect the eating qualities of the tubers. This complaint is physiological and is usually attributed to mechanical injury by the soil.

Protection of Dahlia Tubers: *H.* Plants of Dahlias grown from old tubers keep through the winter much better than those from cuttings struck in spring. The chief points to observe are not to let frost damage the stems, to let about a foot of stem remain, not to shake all the soil from the tubers in lifting—dry soil being a good preservative—and to store the roots in a dry, frost-proof room or cellar. A thick layer of chaff, Beech leaves, or Cocoanut-fibre refuse will act as perfect preservatives of ground plants.

Sulphate of Ammonia as a Dressing for Lawns: *H. T. W.* You would not be well advised to apply sulphate of ammonia in the autumn, but we recommend you to give the lawn a dressing of basic slag now and use the ammonia fertiliser in the spring at the rate of about half an ounce to the square yard. Nitrogenous fertilisers encourage the growth of Grasses, which in time will crowd out the weeds. The application may be made at fortnightly intervals in the spring.

Tomatos Diseased: *T. R.* The roots of your Tomato plants are badly infested with eelworm. We advise you to lift every portion of the roots from the soil and, together with the plants, destroy them by burning. The soil will be infected for another crop, and we advise you to remove all the old compost from the border and substitute fresh soil that has been sterilised by baking. The old soil that is removed should not be placed near growing crops, but buried very deeply in an out of the way part of the garden.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 45.0°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, October 31, 10 a.m.: Bar. 30.25; temp., 52°. Weather—Bright.

Rust of Wheat. So long ago as 1907, Prof. Biffin discovered that resistance to Stripe Rust (Puccinia glumarum) is a character which, like many others possessed by plants and animals, is handed on from parent to offspring. He showed, moreover, that resistance to this rust fungus reappears in the second generation of a cross between a resistant and a susceptible variety of Wheat. Yet in spite of this discovery epidemics of rust still afflict the Wheat crops of the world, reducing yields by so much as fifty per cent. Thus in Minnesota during the ten-year period 1911-1920, rust was epidemic in three years, 1916, 1919 and 1920. In the years when rust was not epidemic the average yield of spring Wheat was 15.4 bushels per acre; in the rust-epidemic years it was only 8.6 bushels per acre, truly a case, so far as farming profits are concerned, of the lean kine devouring the fat kine. An impatient person, knowing but little of rusts or research, might conclude in view of these facts that all the labours of science in relation to the suppression of rust have been in vain. Such a conclusion is singularly ill founded. In order to show how erroneous it is, a brief account is given of recent progress* on the experimental investigations of rust and rust resistance. The problem of preventing attack by rust is a complex one, for there are several different species of rust fungus parasitic on Wheat. There is the Stripe Rust fungus, Puccinia glumarum, which is that investigated by Prof. Biffin in the researches already referred to; there is the Crown Rust, Puccinia coronarum, and the Black Stem rust, P. graminis, which though responsible for less damage to Wheat in this country than is caused by certain other rusts, works havoc, as has been shown in crops of spring Wheat in Minnesota. Each of these parasitic species does evil after its kind, and the power, unfortunately, of resistance to attack by one species does not mean power of resistance to all. Hence the plant breeder who desires to endow the world with rust-resistant varieties of Wheat must be content to deal with one rust at a time. Along these lines good progress has been made and it is well known that hybrid varieties of Wheat have been produced at Cambridge by Prof. Biffin which combined resistance to Puccinia glumarum—Stripe Rust—with other desirable qualities. These resistant varieties retain their resistance generation after generation. But in the case of other rusts, P. graminis, for example, it appears from the researches of Messrs. Hayes and Stakman (*loc. cit.*) and other investigations that the problem of resistance is not so simple. The reasons why the solution is proving more difficult are two: the versatility of the rust species and the sterility of potentially resistant hybrids. Puccinia graminis, among the recognised multitude of fungi known to bring about disease in plants, was one of the first to be discovered. So long ago as the seventeenth century, relation was discovered between the presence of the Barberry and the prevalence of the pest, and laws were passed both in France and North America requiring the extirpation of the common Barberry from the neighbourhood of corn-land—laws which it is to be feared were more honoured in the breach than the observance. In any case, Puccinia graminis, which is now known to belong to that class of organism to which a change is essential, still flourishes. It spends the spring of each year in the Barberry, goes away for the summer to the Wheat field, does nothing in the winter and resumes its Barberry existence in the following spring. Whether it is due to the stimulating effect of change of habitat or to some other cause is not known, but the fact is certain that Puccinia graminis is a species composed of numerous races and that these different biological races may be distinguished from one another if not by size, or shape, or colour, yet by their power of attacking the Wheat plant. It is as though some were more savage than others—able to enter and maintain themselves in the tissues of a given variety of Wheat, whereas a less savage race of the rust might not enter alive. This being the case the problem of breeding varieties of Wheat which shall possess powers of resistance to P. graminis becomes at once clearer and more complex. Restated, it means the breeding of Wheat varieties resistant to all—including the most "savage"—biological races of Black Stem rust known to occur in the country in which the Wheat is to be grown. To do this, however, means that the different biological races have to be discovered and their powers of infecting Wheat of the varieties to be used for cross breeding have then to be ascertained. The magnitude of this task on which Messrs. Hayes and Stakman are engaged may be judged from the fact that the number of biologic races of P. graminis is very large—in Minnesota upwards of thirty-six races have been isolated. Fortunately, the races, although numerous, appear to be stable. Their appetite does not, as was once believed, grow by what it feeds on; in other words, a race does not apparently work itself up into a state of greater virulence by living on a variety of Wheat which falls an easy victim to it. Each race appears to retain a fixed power of infection so that it may be investigated, ticketed and put away for further experimental use. Once a set of the biological races has been obtained and their relative powers of infecting a variety of Wheat ascertained, it is, of course, easy to ascertain, *e.g.*, by cultivating a few seedling Wheat plants in a greenhouse, the degree of resistance of other varieties (and species) of Wheat. This the authors have done in the case of several varieties of common Wheat. It is a relief to find from the result of their experiments that varieties exist (of winter Wheat) which are absolutely immune to nearly all the biological races of P. graminis; such a variety is Kanrid, used for breeding purposes. This variety was crossed with Marquis—which is a susceptible spring Wheat. In the third generation varieties were obtained which combined the "earliness" of Marquis with the resistance of Kanrid. Investigations carried out by inoculating seedlings with spores of the different biological races of P. graminis show that varieties belonging to certain types of Wheat, *e.g.*, Triticum durum and T. dicoccum, also possess great powers of resistance to the rust, but the difficulty of making use of this desirable quality is rendered very great by reason of the high degree of sterility which exists in the hybrids between these types of Wheat and those of common Wheat. Nevertheless, in spite of the complexity of the problem, such good progress is being made towards its final solution that the more sanguine, at all events, may hope that there may come a time even in this world when moth and rust shall not prevail.

* "Wheat Stem Rust from the Standpoint of Plant Breeding." By H. K. Hayes and E. C. Stakman. Minnesota Experiment Station. No. 360. *Journal Series.*

John Snell Memorial Medal.—The National Institute of Agricultural Botany announces that the medal to commemorate the late Mr. John Snell has been awarded for the year 1922 to Mr. G. C. Gough, an Inspector of the Ministry of Agriculture, in recognition of the fact that the full development of immune forms of Potatos was due to his original observations of the existence of immune forms in certain infected gardens.

Henry Eckford Memorial Medal.—On the occasion of the Annual General Meeting of the National Sweet Pea Society, held at the Royal Horticultural Hall, Westminster, on Tuesday, the 30th ult., the announcement was made that the Trustees of the Henry Eckford Memorial Fund had awarded the Henry Eckford Memorial Medal for 1923 to Mr. Charles H. Curtis, Managing Editor of the *Gardeners' Chronicle*, for "good work done in connection with Sweet Peas." Mr. Curtis was one of the founders of the N.S.P.S., and for many years acted as its Hon. Secretary; during the year just ended, and during the Society's coming-of-age year, he was Chairman of Committee. He has also been Chairman of the Society's Floral Committee, and in former years was one of the Editors of the Society's *Annual*.

Celmisias and Olearias.—A neat little booklet dealing with two prominent genera of New Zealand plants* has been issued by the *Otago Daily Times*. These genera are Celmisia and Olearia, and the former is dealt with in a most interesting manner by Sir G. Fenwick, whose contribution gains additional interest from the copious notes by Mr. James Speden, an acknowledged authority on these Mountain Daisies of New Zealand. Nine illustrations accompany the text, in which about two dozen species are described. Sir G. Fenwick writes

* *New Zealand Native Flora.* 1, Celmisias, by Sir G. Fenwick; 2, Olearias, by James Speden. Otago Daily Times and Witness Newspapers Co., Ltd., Dunedin, New Zealand.

Digitized by Google

in high praise of the fine spirit of those men who year by year make trips to those scattered regions where Celmisias and other alpine plants may be found. He quotes from one collector who was successful in obtaining plants of Celmisia Adamsii at Coromandel: "Sunday dawned bright and fair—a rarity at this time of the year here. At about 9 a.m., I set out on a horse from the stables, rode six miles and then walked along a spur for two or three miles to the edge of the bush, headed for the top. I believe there is a track through, but I never struck it. After a very short climb, to my surprise I found myself at the base of the castle-like rocks, which stand out boldly on the summit. Here, within fifty or one hundred feet of the top, grew about a dozen plants of Celmisia Adamsii, the only ones as far as I could see. Their location was in the crevices of the rocks. The height of Castle Rock is 1,250 feet. On the way back I got bushed, and fell down several mine shafts or depressions which were overgrown with scrub; but I got back safely about 8 p.m. A search party had been sent out for me, but I missed them, having struck out of the bush several miles to the right." The second part of the booklet is concerned with Olearias, and is from the pen of Mr. James Speden, who occupies ten of its forty-two pages. Twenty-one species are described, and the one most popular in the British Isles, O. Haastii, is disposed of in a few words, as though it does not compare favourably with other kinds in its native home. Mr. Speden refers to O. Forsteri (the Akiaho), as being usually grown as a hedge plant, but it also "makes a beautiful shrub or small tree, with lovely, light green foliage, and although the flowers are not conspicuous, they give off a fine fragrance. As an ornamental hedge plant up to four feet high, it is the prettiest thing that I know." The wide range of difference is noted between certain species, *i.e.*, O. insignis and O. fragrantissima, O. lacunosa and O. nitida, O. virgata and O. Colensoi, and O. operina and O. nummularifolia var. cymbifolia. Mr. Speden adds: "There is one thing about most of the species which strikes us all the first time we see them in flower, that is, their delicious fragrance." Those who cultivate Celmisias and Olearias in Great Britain and Ireland will accord this little book a hearty welcome.

Summer Time, 1924.—The Early Closing Association organised a deputation to meet the Home Secretary on Wednesday, October 31, for the purpose of urging the extension of summer time in 1924. Besides employers and employees in wholesale and retail distributing trades, the deputation included allotment holders, athletes, boat builders, and visitors to public parks and gardens. Sir Kingsley Wood, Parliamentary chairman of the Association, introduced the deputation.

Leaflets on the Cultivation of Brassicas.—The Ministry of Agriculture has published two leaflets on the cultivation and marketing of Cabbages and Savoys, and Brussels Sprouts respectively. The Cabbages are classified by the writer into four groups, those with pointed heads, the drum-headed type, Savoys and Red Cabbages. The best time recommended for sowing seed of Spring Cabbages is from the 23rd-25th July in the Eastern Counties, the last week in July in Worcestershire, the end of July or early in August in Kent, and the 1st-5th of August in Middlesex. The earliest plants of the first sowing would, it is stated, be ready to plant in the third week in September, and these earliest plants may be set from nine to ten inches apart, whilst for later cutting October planting is recommended, putting the plants from twelve to fifteen inches asunder, allowing some a greater distance—fifteen to eighteen inches, to be left to stand for summer Cabbages. With respect to Brussel Sprouts, raising the plants early in cold frames is recommended to obtain as long a growing season as possible, which, in our opinion, is most essential with this crop. The practice of sowing the seeds in September or early in October and planting the seedlings in April is condemned, as the method is said to fail frequently. Brussels Sprouts require plenty of manure, and before the seed is sown or the plants set phosphates and potash should be applied to the soil. On light soils it is recommended to use five hundredweights per acre of bone meal or steamed bone flour, together with four hundredweights per acre of kainit, and on heavy soils five to ten hundredweights of good fish guano. When the plants are well established a top dressing of nitrate of soda at the rate of two hundredweights per acre is recommended.

Mr. T. Pateman.—Mr. T. Pateman, whose success as a gardener is well known to most of our readers, has had the happy experience of remaining almost continuously in the one garden during the whole of his professional career. As most readers are aware, Mr. Pateman is gardener to Sir Charles Nall-Cain, who has recently purchased the estate of Brocket Hall, Hertfordshire, quite close to his old residence at The Node, Welwyn. Mr. Pateman commenced his career in the latter gardens and remained there for nearly six years, serving under three Scotch and two English gardeners. He left

MR. T. PATEMAN.

The Node to gain further experience at Little Heath House, where the gardener was Mr. Foulger, a noted cultivator of florists' flowers. Subsequently Mr. Pateman became gardener to Montague Price, Esq., at the Manor House, Knebworth, but in 1896 he returned to The Node, as gardener to the same gentleman. The Node estate was purchased by Sir Charles Nall-Cain in 1909, and Mr. Pateman continued in his service as gardener, and he has served the same employer ever since. When he took charge of The Node gardens, the whole of the place was in a much neglected condition, and offered scope for such an enthusiastic and skilful cultivator as Mr. Pateman, to show his abilities in reorganising the place. Most of the hardy fruit trees were grubbed up, and the whole of the fruit and kitchen gardens trenched about three feet deep. Fresh fruit trees were planted, and new glasshouses erected, so that in a short time The Node gardens ranked amongst the finest in the country. Mr. Pateman has met with remarkable success as an exhibitor; he has won five hundred and fourteen first prizes, two hundred and sixty second prizes, and one hundred and fifty-eight third prizes. In 1915 he was awarded four Standard Cups at one of the R.H.S. exhibitions on the one day. Beside fruits, Mr. Pateman ranks amongst the foremost cultivators of plants, and exhibits of Begonias from The Node have been awarded Gold Medals at the Royal Horticultural Society's meetings. He is also a prominent exhibitor at important Chrysanthemum exhibitions. At the recent Holland Park show he won the Hogg Medal for a collection of choice indoor fruits, and the Silver-gilt Medal of the Worshipful Company of Fruiterers for a collection of twenty-four dishes of Apples, besides numerous other prizes. Mr. Pateman has a keen eye for the beautiful, and the improvements which are being effected in the gardens and estate at Brocket Hall under his supervision promise to restore this famous old estate to its former rank as one of the show places of the country.

National Potato Exhibition.—The National Potato Society of Great Britain and Ireland will hold its exhibition at Bingley Hall, Birmingham, in conjunction with the annual exhibition of the Birmingham Chrysanthemum Society, on Tuesday, Wednesday and Thursday, November 6, 7 and 8.

Journal of the Royal Horticultural Society.—The *Journal* of the Royal Horticultural Society, Vol. XLVIII., Parts 2 and 3, contains much matter of interest, including articles on "Autumn Crocuses," by Mr. E. A. Bowles; "Anglo-Saxon Plant-lore," by Miss Eleanour Sinclair Rohde; "Some Early Italian Gardening Books," by Mr. E. A. Bunyard; "Methods of Propagation in an Amateur's Garden," by Mr. C. T. Musgrave; "The Flora of the Tibetan Marches," by Mr. F. Kingdon Ward; and "Some Hardy Bulbs," by the Rt. Hon. Sir Herbert Maxwell. There are also descriptions of the following plants, which have received the Award of Garden Merit:—Viburnum fragrans, Jasminum nudiflorum, Hyacinthus azureus, Tulipa Kaufmanniana, Forsythia intermedia spectabilis, Osmanthus Delavayi, Viburnum Carlesii, Corylopsis pauciflora, Pyrus floribunda, Pyrus × purpurea, Berberis × stenophylla, Magnolia stellata, Philadelphus grandiflorus, Genista virgata, Spartium junceum and Genista aethnensis. The *Journal* gives the results of trials at Wisley in 1921-22 and 1923, and the proceedings of the various Committees from July to December, 1922, and also the deliberations of the Narcissus and Tulip Committee from February to May, 1922.

The Potato Crop.—According to the International Institute of Agriculture of Rome the crop of Potatos generally shows a decrease of 18 per cent. From data furnished by countries representing slightly over half of the world's production, it is estimated that the total yield will be 65.5 million metric tons, as compared with 80.1 million metric tons last year, which, however, was one of the best years for Potatos within memory.

Hailstorm Damage in Colorado.—According to our American contemporary, the *Seed World*, a destructive hailstorm occurred on a limited area at Rocky Ford, Colorado, in August last. The storm destroyed crops of Maize and Cantaloup Melons over an area eight miles long, and one-third of a mile wide. An illustration shows Maize stripped to the stem, or beaten to the ground, and the soil so thickly covered with hailstones as to present a winter snow scene.

New Secretary of the Chamber of Horticulture.—We understand that Mr. S. W. Hale, formerly Assistant Secretary, has been appointed Secretary of the Chamber of Horticulture in succession to Mr. C. M. Matthews.

The Hop Crop.—The total production of Hops in this country for 1923 is estimated at 229,000 cwt., which is 72,000 cwt. less than in 1922, and 38,000 cwt. below the average production in the 10 years 1913-22. In the south-eastern counties the yields per acre are considerably lower than those of 1922, particularly in Sussex, where the crop of the preceding year was very heavy. In Kent the yield is 2½ cwt. per acre less than in 1922, and 1½ cwt. per acre lighter than the mean of the previous ten years. Yields in the western counties are, on the whole, rather better than in 1922, the Worcestershire crop being ½ cwt. per acre heavier than that of last year, which was an average crop, and the yield in Hereford is of practically the same weight per acre as in 1922, and about ½ cwt. short of the ten-year mean.

European Orchids. — The *Album of European Orchids*, published in 1889, and already out of print by 1905, has been so frequently asked for since that date that the author, M. Henri Correvon, of Floraire, Chêne-Bourg, Geneva, has decided to bring out a new edition, with six fresh plates in colour from originals by M. Godfrey, representing seven species from the Mediterranean littoral. Thus 67 species of European Orchids are illustrated in 66 plates, with descriptive text. The text in the new edition has been slightly abridged. The price, to purchasers obtaining copies before December 31, 1923, will be the same as in 1899, namely 20 francs; from January 1, 1924, onwards, the volume will be sold at 25 francs. The coloured plates, admirably produced, comprise a complete representation of all the Orchids indigenous to Europe, except some types of Ophrys, Serapias, etc., belonging to the most southerly regions of Italy, Greece, and Spain.

Appointments for the Ensuing Week.—Sunday, November 4: Wakefield Tulip Society's meeting. Tuesday, November 6: National Potato Show in conjunction with the Birmingham Chrysanthemum Society's show (three days); West of England Chrysanthemum Society's show (two days); Brighton, Hove and Sussex Horticultural Society's show (two days); Royal Caledonian Horticultural Society's meeting. Wednesday, November 7: Royal Oxfordshire Horticultural Society's show (two days); Forest Hill Chrysanthemum Society's show; Mitcham, Tooting and District Horticultural Society's show; Sevenoaks Chrysanthemum Society's show; Marlow and District Chrysanthemum Society's show; Guildford and District Chrysanthemum Society's show (two days); Gainsborough Chrysanthemum Society's show (two days). Thursday, November 8: Bedford and District Chrysanthemum Society's show; Jersey Gardeners' Chrysanthemum Society's show; Finchley Chrysanthemum Society's show (two days); Hitchin Chrysanthemum Society's show; Taunton and District Chrysanthemum Society's show; Nottingham and Notts Chrysanthemum Society's show (three days); Coventry and District Chrysanthemum Society's show (three days); Doncaster and District Chrysanthemum Society's show (three days). Friday, November 9: Gloucestershire, Root and Fruit Society's show; Derbyshire Gardeners' Association's Chrysanthemum show (two days); Sheffield Chrysanthemum Society's show (two days). Saturday, November 10: Hawick Horticultural Society's show; Burton-on-Trent and Shobnall Chrysanthemum Society's show; Accrington and District Chrysanthemum Society's show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Japan Lilies.* Has it ever been remarked that all the varieties of Lilium lancifolium degenerate or go back to the white variety? For these last three years I flowered with success L. l. album, l. punctatum, and l. roseum, all of which, in November, 1847, were repotted as usual by myself. My stock consisted of four pots of L. l. album, two of punctatum, and one of roseum. This autumn all the seven plants have produced white flowers! I may state that I am my own flower gardener, and that it is impossible that any substitution of roots could have taken place, and that the pot of L. l. roseum was remarkable and unmistakeable, from the following circumstance: I had originally received the plant from Mr. Van Houtte, of Ghent. Observing that it had been grown in pure black peat, or rather heath soil, I always replanted it, and that bulb alone, in similar soil: therefore, without any label, that particular pot was always distinguishable, and so it continues to be at this moment. I would further observe that in making its growth this summer, the ex L. l. roseum retained its former dwarf habit, flowering at the height of about 2½ ft., whilst all my true L. l. album attained as usual an altitude of nearly five feet. *H. D., Junr., Beau Séjour, Guernsey, October* 15. *Gard. Chron., October* 28, 1848.

HARDY FLOWER BORDER.

A LARGE ANTIRRHINUM PLANT.

DOES any record exist of a bigger plant of Antirrhinum than the one illustrated herewith (Fig. 93)? The plant first appeared as a self-sown seedling in the kitchen garden here last year, growing to an average size and flowering as usual. It was left undisturbed and continued to increase in size early this season until at the time it was photographed it carried upwards of 300 flower spikes, large and small. It measured 3 ft. 6 in. across one way and 3 ft. another way, and was approximately 7 ft. in circumference. Being a rounded plant only the flowers of one side and the top spikes are visible in the picture. Around the base of the plant a cluster of young growths has appeared, while the whole root-stock looks extremely vigorous and the top is still green.

Two other Antirrhinum fine plants came up in other parts of the garden—self-sown—one carrying about 30 spikes and the other 50 spikes.—*C. Turner, Ampthill Park Gardens, Bedfordshire.*

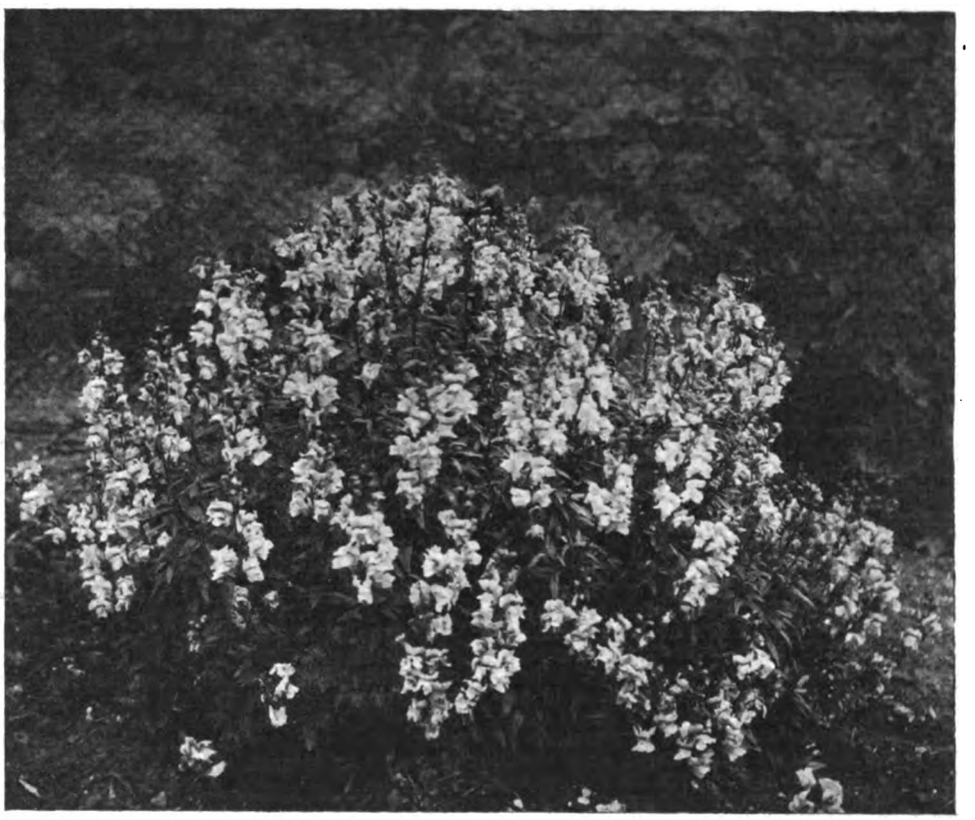

FIG. 93.—A LARGE, SELF-SOWN ANTIRRHINUM.

RHEUM NOBILE.

I SEND a photograph (Fig. 94) of a plant of Rheum nobile, which flowered in the Royal Botanic Garden at Edinburgh either in 1886 or 1887, which hitherto has not been published. I am not quite certain whether it was in the former or the latter year that it flowered. It was in the spring of 1886 that I commenced photography, and as the negative is on a 5 by 4 plate, which size I discarded for the quarter plate in the following year, it could not have been later than 1887. The label attached to the plant bears, in the handwriting of the late Mr. Robert Lindsay, the Curator of the garden at that time, the following inscription—"Rheum nobile, Hook. fil., Sikkim (H. J. Elwes, Esq., 1882)." The date, 1882, would no doubt refer to the year in which the seed was received from Mr. Elwes, so that four or five years must have elapsed between the sowing of the seed and the flowering of the plant.

I have a quite vivid recollection of the plant, which would, I think, be somewhere between four and five feet in height, and the flower stem, with its delicate, beautifully imbricating bracts of a pale straw colour, with a slight tinge of pink at the edges in the upper part of the spike, formed an almost perfect cone arising from the centre of a ring of large, glossy-green normal foliage leaves at the base.

It would be interesting to know if any other plants of this species have flowered in this country. It is a remarkably beautiful plant when in flower, or rather when it produces its flowering stem, for the flowers themselves are quite inconspicuous. *A. D. Richardson, Edinburgh.*

[Rheum nobile flowered in the Royal Botanic Garden, Edinburgh, in 1880, and an illustration of the plant was given in *Gard. Chron.*, June 19, 1880, Fig. 138.—EDS.].

HARDY GERANIUMS IN AUTUMN.

MANY of the hardy Geraniums may be counted upon to give colour at this season, and the best of them is G. Wallichianum, var. E. C. Buxton, whose clear blue, white-centred flowers never look so charming as they do in the waning light of these shortening days. This plant is, of course, by nature a somewhat late bloomer, but the much earlier G. grandiflorum is also an autumn flowerer of no small merit, its large, blue-purple blossoms adorning the handsome foliage which freshens up with renewed vigour when the autumnal rains begin.

G. Endressii, with flowers of a full-toned pink, also revives at this season, and the prettily veined blossoms of G. striatum are doubly welcome at a season when flowers grow daily fewer.

Then there are the numerous hybrid offspring which these two Geraniums produce and which, in every conceivable shade of pink, appear as self-sown seedlings to brighten the woodland and garden until winter has approached.

Where it does well G. Traversii will often yield some lovely blossoms in October, but those who are unable to grow this somewhat fastidious plant will find in its offshoot, G. "Russell Pritchard" an admirable substitute of most remarkable vigour and one that will be in bloom with the very last. *N. Wales.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Temperatures.—The following temperatures should now be maintained: East Indian house, 60° to 70°; Cattleya house, 55° to 60°; Mexican and intermediate house, 50° to 60°; cool house, 45° to 50°. No harm will follow if the temperatures fall a few degrees lower for a short period during periods of extreme cold or high wind. For the next few months the heating apparatus will have to provide most of the warmth in the various houses, and it should be used carefully. Most plant diseases are attributable to faulty conditions of temperature of the houses in which the plants are grown. The injurious effects of artificial heat during unusually cold weather should be so far as possible counterbalanced by the admission of fresh air, and the use of a moderate amount of water in damping the paths, stages, and immediately under and around the pipes. In order to economise heat, it is a good practice to cover the house with canvas or lath roller blinds, which may be let down whenever necessary; these make a considerable difference to the temperature. In cold, windy weather these coverings should be made secure, so that they cannot break the glass. Canvas blinds should only be placed on the hottest houses, as it often happens that they become frozen so stiff on cool houses that they cannot be rolled up again for several hours, and the plants may thus lose a considerable amount of light, of which Orchids never have enough during the short winter days. Wash the glass periodically, especially if the houses are near trees or the gardens near big towns. cleanliness is one of the greatest aids to good cultivation, and should be practised in all departments.

General Remarks.—November is the period when the winter treatment of Orchids should commence. Light, heat, moisture, and air must be so utilised that the growing plants may be encouraged to mature sound, healthy growth, whilst those which are at rest are not unduly excited. Natural light is beyond our control, but heat, moisture, and air are not; it follows, therefore, that we must use those three in proportion to what we receive of the other. During the winter months the temperatures of the various houses on light, bright days should be a few degrees higher than on dull, heavy days; and the highest temperature of any house should be attained between the hours of noon and two p.m., while the lowest reading should be during the hours of darkness. The difference between the two extremes should be from 5° to 10°, when the temperatures are maintained by fire heat, but several degrees higher may be allowed during sunshine. Sudden fluctuations of temperatures should be prevented as much as possible, for many Orchids are easily injured. Excessive fire heat is harmful; so also is a damp atmosphere and low temperature, especially during the winter months.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Fruit Storage.—The gathering of late keeping Apples now being completed, every care must be taken of the fruits stored during the first few weeks. Decaying fruits should be removed immediately they are seen. Make sure there is a free circulation of air during the "sweating" period. Airing the house as much as possible in the early days, and as little as possible later, is a good plan to follow. Should the fruits shrivel, it means they have been gathered too early, or are stored in too dry an atmosphere. The difficulty of keeping mice out of a storeroom often presents itself. We have recently adopted a plan which we hope will effectively prevent these vermin from finding an entrance. The windows open outwards. A square framework is built out from the sill equal to the width and height of window, etc. Over this frame small-mesh wire is fixed. The window thus opens in, as it were, a wire cage. Perforated zinc has the disadvantage of not allowing a sufficiently free passage for air. Extra care should be given to fruit to be stored in litter, sand, or other medium until early summer. Late keeping varieties should be carefully selected, and only thoroughly sound fruit used. Certain cooking varieties, such as Newton Wonder, are quite good for dessert should other sorts not be available during May and June. From March to June there are several dessert kinds, which include Easter Orange, Court Pendu Plat, King's Acre Pippin, Lord Hindlip, and Sturmer Pippin.

Planting.—With the completion of lifting trees with gross wood, every effort should be made to be ready for the arrival of trees from the nurseryman. In planting, whether on walls or in the open, a record should be made of the position of each tree, as labels often get misplaced, or blown off by wind. For general instruction it is a good plan to write the year of planting on the label.

Selection of Site.—Apart from larger areas for orchards, there is always some hesitancy, especially in small gardens, regarding the best place in which to plant fruit trees. The old way of placing espalier-trained trees and Currant bushes round—and a few feet distant from—the paths, does not find so much favour now. It is certainly better to have fruits that birds are fond of planted all together. Trees planted together may also be treated alike in regard to manuring, liming and mulching. The pyramidal or cone-shaped tree is now superseded by the open trained bush. These trees are more easily managed, both when pruning and when gathering the fruit. To those who desire the introduction of more highly-coloured autumn foliage and fruit in the shrubberies, the cone-shaped trees will make an appeal.

PLANTS UNDER GLASS.

By JOHN COUPER, Assistant Curator, Royal Botanic Gardens, Kew.

Orange Trees.—Gardeners generally regard Orange trees as dirty plants, as they commonly suffer from attacks of scale, and frequent sponging is necessary to keep them clean. However, by frequent spraying with a paraffin and soft soap emulsion the attacks of scale may be largely prevented or reduced.

Pernettya mucronata.—Well fruited plants of this hardy evergreen shrub are very bright and useful for furnishing the cool greenhouse during the winter months. The plants should now be placed in pots of suitable size, using a compost consisting of light loam and peat for potting purposes. After they have done duty in the greenhouse they may be planted out in the reserve garden for future use; if it is desired to keep the plants small they should be divided before they are planted out.

Aucuba japonica vera.—Small Aucuba plants well covered with fruit are very showy in the cool greenhouse during the dull season. They may be lifted from the open ground now and placed in pots, or they may be pot grown, but are less trouble if they are planted out during the growing season. As this species is dioecious, a few male plants should be grown to ensure a free set of fruit. Well-berried plants of Skimmia are also very useful.

Helleborus niger.—Good, strong plants of this Christmas Rose are serviceable for the cool greenhouse, and may now be placed in pots. If they are required in quantity for a supply of cut flowers, they may be covered where they are growing with handlights or frames. This is necessary to keep the flowers clean. Slugs frequently prove troublesome and soon spoil the flowers; the pests should be sought for and destroyed.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Endive.—Plants of late sown Endive should now be lifted and placed in cold frames, or in cold fruit houses, if the former are not available. If the latter are used, place some old potting soil on the borders to plant the Endive in, so as not to injure any fruit tree roots that may be near the surface. The Endive may then be blanched by placing a 6-inch pot over each plant, first carefully folding the outer leaves. Plants in frames coming to maturity should be kept clear of dead leaves and loosely tied up to assist blanching. If watering is necessary, do this in the morning on a bright, windy day if possible, so that the plants become dry before night.

Globe Artichokes.—It is wise to provide young plants if fine heads are desired; now is a good time to dig up some strong suckers from the sides of the old plants, and place them in 8-inch pots. When finished give a good watering, and place them in a frame where they may receive plenty of air and yet be protected from severe frosts. The plants in the bed should have all rubbish cleared away from them, and a good dressing of half-decayed manure placed round them. In the event of sharp frosts cover them with Bracken or long litter, removing these when the weather becomes warmer.

Jerusalem Artichokes.—The stems of Artichokes may be cut down, and sufficient for present use be dug up and stored in sand. Use the largest and best shaped tubers, and save the small ones for planting next season. The white variety is much superior in every respect to the old purple-skinned Artichoke.

Asparagus.—The stems of Asparagus will now be ripe, and should be cut close to the ground. The beds may then have a final cleaning, and during dry or frosty weather receive a good top-dressing of well-rotted manure. The winter rains will wash the nutriment down to the roots, thus benefiting the plants greatly, and assisting them to develop strong crowns for next season.

Vegetables in Store.—On wet days examine the crop of Onions, and remove for present use any specimens that are not quite sound, and turn the others over carefully, allowing as much room as possible between them. Onions quickly deteriorate if stored in a damp place, therefore the driest situation possible should be reserved for them. Examine the Potatos and remove any that are diseased or in any way faulty, at the same time picking out any that are required for seed purposes, placing these upright in shallow trays, and remove them to a light frost-proof shed. Carrots, Beets and Turnips stored in sand or soil outside should not be allowed to become too wet; place some sheets of corrugated iron over them to ward off heavy rains, or, failing this, place a good straw thatch over the heaps.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BURNERS, Esq., Woolverstone Park Gardens, Ipswich.

Late Vineries.—Afford the Grapes in these vineries an even, cool, dry atmosphere. Water tanks, unless well covered over, should be emptied. No other plants should be housed in these vineries, or anything likely to create a damp atmosphere while the bunches are hanging. Use sufficient fire heat only to prevent a damp atmosphere, and admit air through the bottom and top ventilators, regulating the amount according to the weather. The bunches should be examined frequently, and have all decaying berries removed. The borders, if inside, should not be allowed to become too dry; when water is necessary, choose a fine day for watering, and keep the ventilators wide open throughout the day, with a good circulation of warmth in the pipes. Outside borders should be covered with material that will ward off rain. The night temperature should not be allowed to fall below 45° in cold weather.

Digitized by Google

Cucumbers.—Late Cucumbers growing in houses for late autumn and winter cropping will need special attention from now onwards. The glass and woodwork should be thoroughly cleansed, and the plants grown in plenty of heat and moisture. The beds should not be too large; it is better to add fresh, rich soil occasionally. The shoots of the plants should be kept well thinned, and tied to the trellis. Very little ventilation will be needed, just a small amount of fresh air on bright mornings, but the house should be closed again soon after noon. Fumigate the house occasionally, to keep the plants clean, and do not syringe the latter on dull days; rather damp the walls and floors thoroughly to promote atmospheric moisture.

Pot Vines.—Vines soon to be started may now be repotted or top-dressed. If they require more root room they should be placed in pots large enough for their requirements, and the compost should consist of good turfy loam (that which has been stacked for a year or more is the best for the purpose), bone meal, and sufficient broken plaster or mortar rubble to ensure porosity; manure is not required, as nutriment can be supplied when the plants require further assistance. The pots used should be scrupulously clean, and the drainage material carefully arranged; it is not their quantity so much as the manner in which the crocks are arranged that ensures perfect drainage. Pot firmly, and leave ample space for a good supply of water. When the pots are plunged and the vines started, tie the canes half-hoop fashion, as this will cause them to break evenly. The vines may be dressed for insect pests, as advised for pot Figs, and the same remarks are applicable respecting the provision of bottom heat, temperature, etc.

THE FLOWER GARDEN.

By C. TURNER, Gardener to EMILY, LADY AMPTHILL, Ampthill Park, Ampthill, Bedfordshire.

Roses in Woodlands.—Many Roses are well adapted for planting in those woodlands or semi-wild parts of gardens found in the majority of garden enclosures. Certain species and varieties are better suited for such positions than for the trim and often unavoidably more confined places they are planted in. Under these conditions the plants may be allowed more freedom, which in most cases improves their effect, and in all instances is in perfect keeping with wild garden surroundings. Roses so grown may be loosely secured to rough tripods, branches of trees fixed in the ground to act as supports, encouraged to cover old tree stumps, or be trained against the trunk of a dead tree that has been left standing. Planted as bushes in the open ground, without support, many kinds produce a delightfully natural feature that is particularly attractive if the site occupied be sloping ground. The chief points to be kept in view when planting under these rougher conditions are an avoidance of shade, and to see that the plants have a fair start. Some Roses suitable for either or all of the above purposes which I strongly recommend are:—Carmine Pillar, Crimson Rambler, Dundee Rambler, Felicité Perpetue, Gardenia, Jersey Beauty, Madame Plantier (excellent for grouping), Réné André, Una and Wichuraiana. Other types available for grouping in woodland spaces are the rugosa Roses and Penzance Briars, while they also form good hedges. Rose Hugonis is another strong-growing species useful for the latter purpose, and for planting in shrubberies.

Rose Cuttings.—Practically all kinds of Roses may be grown from cuttings, but in view of the cheap prices of Rose plants it is questionable whether time and space necessary to root and transplant them for a year before planting permanently is justifiable. Some years ago I experimented with many varieties in this way, and with a fair measure of success, with strong growing sorts; but weak growing varieties were too slow in becoming large plants. An illustration of Caroline Testout was given in *Gard. Chron.* at that time, showing the result of this variety on its own roots. Cuttings may be put in now, where there is a wish to do so, in open ground.

NOTES FROM TORQUAY.

EUPATORIUM glabratum is a name under which a very distinct and pleasing species of Eupatorium—tender no doubt in most parts of the country—is not uncommonly grown. It forms a dense growing, roundish shrub which I have seen up to the height of five or six feet; the leaves are somewhat oval, perhaps three inches long, tapering at both ends, firm in texture and very shiny. The small, white, rayless flower-heads form loose cymes and are produced very freely in later summer, about late October. It is a quietly ornamental shrub and lends itself as well as anything to the rough and ready method of pruning by trimming up with shears, which I have noticed in use for a whole collection of shrubs bordering a walk!

Leycesteria formosa is a well-known shrub, and although it does its best to live in various parts of the country it is rarely seen in a satisfactory condition, except under very special circumstances or in localities at least as mild as Torquay. At Cambridge it was always nipped back and rendered stubby by cold, but I do not think it ever died. Here it is sometimes very striking, and one sees what it may become with a little care. There may be circumstances under which it requires to be cut back, but as a rule it requires regulation rather than pruning, and certainly its appearance would be ruined by the treatment which the Eupatorium seems not much to mind. Shoots no doubt may sometimes be thinned with advantage, and useless growth may perhaps be cut away, the object being to produce those strong and graceful natural shoots and branches which arch over and carry the pendulous racemes under a canopy of bright green foliage. The fairly old stems are bright green, and there is nothing among shrubs to surpass in attractiveness the lively green of the leaves. These are several inches in length, quite smooth, ovate-lanceolate in outline, but variable, strongly acuminate, with reddish petioles, mid-rib and margin.

The pendulous racemes which give the plant its characteristic effect are both terminal and axillary; the purplish-red bracts are large and broad at the base of the raceme and taper in size down to its point; they are now strung along with the red fruits like a piece of necklace, on slender stems in place of string, in short bits or on a length of several inches. A few weeks ago—and still they come—the small white corollas were conspicuous against the red setting, but the effect was good, and so it will remain while bracts and fruits last. The planting of this shrub is worth consideration, and from what I have seen I would suggest the planting of several in a large round bed, or in any position which allows the racemes to be seen against a light rather than against a dark background, but wherever it will grow satisfactorily it is worth planting. It is a native of Nepal.

A single flower of Rosa bracteata—the Macartney Rose—on a pot plant in the Rosery Nursery, Torquay, compels me to draw attention to this very fine but much neglected Rose. It is, of course, more or less tender, but many years ago there was a fine specimen on the east side of the wall of the herbaceous ground at Kew, and I remember it for many years in east Cornwall as a shrub under a rustic porch. It is noteworthy if only for its deep green, highly polished, evergreen foliage, but from June to late autumn, when this is contrasted with a profusion of large white flowers, it stands out as one of the finest and most distinct of all Roses. Of somewhat rambling habit, its best place is against a wall where it can attain a height of about 20 feet. The branches are stout and sturdy, well provided with strong, hooked prickles and bristles. The leaves are composed of some five to eleven obovate leaflets, from ¾ inch to 2 inches long and ½ inch to 1 inch wide, of firm texture, with the stipules laciniated. The flowers are handsome in form, three to four inches across, each on its own short stalk and surrounded by several large and downy laciniated bracts; they have a delicate fruity perfume. The calyx tube and sepals, which are ¾ inch long, are covered with a pale brown wool. The fruit, which has a diameter of about 1½ inch, is globose, orange-red and woolly.

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Temperatures.—The following temperatures should now be maintained: East Indian house, 60° to 70°; Cattleya house, 55° to 60°; Mexican and intermediate house, 50° to 60°; cool house, 45° to 50°. No harm will follow if the temperatures fall a few degrees lower for a short period during periods of extreme cold or high wind. For the next few months the heating apparatus will have to provide most of the warmth in the various houses, and it should be used carefully. Most plant diseases are attributable to faulty conditions of temperature of the houses in which the plants are grown. The injurious effects of artificial heat during unusually cold weather should be so far as possible counterbalanced by the admission of fresh air, and the use of a moderate amount of water in damping the paths, stages, and immediately under and around the pipes. In order to economise heat, it is a good practice to cover the house with canvas or lath roller blinds, which may be let down whenever necessary; these make a considerable difference to the temperature. In cold, windy weather these coverings should be made secure, so that they cannot break the glass. Canvas blinds should only be placed on the hottest houses, as it often happens that they become frozen so stiff on cool houses that they cannot be rolled up again for several hours, and the plants may thus lose a considerable amount of light, of which Orchids never have enough during the short winter days. Wash the glass periodically, especially if the houses are near trees or the gardens near big towns. cleanliness is one of the greatest aids to good cultivation, and should be practised in all departments.

General Remarks.—November is the period when the winter treatment of Orchids should commence. Light, heat, moisture, and air must be so utilised that the growing plants may be encouraged to mature sound, healthy growth, whilst those which are at rest are not unduly excited. Natural light is beyond our control, but heat, moisture, and air are not; it follows, therefore, that we must use those three in proportion to what we receive of the other. During the winter months the temperatures of the various houses on light, bright days should be a few degrees higher than on dull, heavy days; and the highest temperature of any house should be attained between the hours of noon and two p.m., while the lowest reading should be during the hours of darkness. The difference between the two extremes should be from 5° to 10°, when the temperatures are maintained by fire heat, but several degrees higher may be allowed during sunshine. Sudden fluctuations of temperatures should be prevented as much as possible, for many Orchids are easily injured. Excessive fire heat is harmful; so also is a damp atmosphere and low temperature, especially during the winter months.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Fruit Storage.—The gathering of late keeping Apples now being completed, every care must be taken of the fruits stored during the first few weeks. Decaying fruits should be removed immediately they are seen. Make sure there is a free circulation of air during the "sweating" period. Airing the house as much as possible in the early days, and as little as possible later, is a good plan to follow. Should the fruits shrivel, it means they have been gathered too early, or are stored in too dry an atmosphere. The difficulty of keeping mice out of a storeroom often presents itself. We have recently adopted a plan which we hope will effectively prevent these vermin from finding an entrance. The windows open outwards. A square framework is built out from the sill equal to the width and height of window, etc. Over this frame small-mesh wire is fixed. The window thus opens in, as it were, a wire cage. Perforated zinc has the disadvantage of not allowing a sufficiently free passage for air. Extra care should be given to fruit to be stored in litter, sand, or other medium until early summer. Late keeping varieties should be carefully selected, and only thoroughly sound fruit used. Certain cooking varieties, such as Newton Wonder, are quite good for dessert should other sorts not be available during May and June. From March to June there are several dessert kinds, which include Easter Orange, Court Pendu Plat, King's Acre Pippin, Lord Hindlip, and Sturmer Pippin.

Planting.—With the completion of lifting trees with gross wood, every effort should be made to be ready for the arrival of trees from the nurseryman. In planting, whether on walls or in the open, a record should be made of the position of each tree, as labels often get misplaced, or blown off by wind. For general instruction it is a good plan to write the year of planting on the label.

Selection of Site.—Apart from larger areas for orchards, there is always some hesitancy, especially in small gardens, regarding the best place in which to plant fruit trees. The old way of placing espalier-trained trees and Currant bushes round—and a few feet distant from—the paths, does not find so much favour now. It is certainly better to have fruits that birds are fond of planted all together. Trees planted together may also be treated alike in regard to manuring, liming and mulching. The pyramidal or cone-shaped tree is now superseded by the open trained bush. These trees are more easily managed, both when pruning and when gathering the fruit. To those who desire the introduction of more highly-coloured autumn foliage and fruit in the shrubberies, the cone-shaped trees will make an appeal.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Orange Trees.—Gardeners generally regard Orange trees as dirty plants, as they commonly suffer from attacks of scale, and frequent sponging is necessary to keep them clean. However, by frequent spraying with a paraffin and soft soap emulsion the attacks of scale may be largely prevented or reduced.

Pernettya mucronata.—Well fruited plants of this hardy evergreen shrub are very bright and useful for furnishing the cool greenhouse during the winter months. The plants should now be placed in pots of suitable size, using a compost consisting of light loam and peat for potting purposes. After they have done duty in the greenhouse they may be planted out in the reserve garden for future use; if it is desired to keep the plants small they should be divided before they are planted out.

Aucuba japonica vera.—Small Aucuba plants well covered with fruit are very showy in the cool greenhouse during the dull season. They may be lifted from the open ground now and placed in pots, or they may be pot grown, but are less trouble if they are planted out during the growing season. As this species is dioecious, a few male plants should be grown to ensure a free set of fruit. Well-berried plants of Skimmia are also very useful.

Helleborus niger.—Good, strong plants of this Christmas Rose are serviceable for the cool greenhouse, and may now be placed in pots. If they are required in quantity for a supply of cut flowers, they may be covered where they are growing with handlights or frames. This is necessary to keep the flowers clean. Slugs frequently prove troublesome and soon spoil the flowers; the pests should be sought for and destroyed.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Endive.—Plants of late sown Endive should now be lifted and placed in cold frames, or in cold fruit houses, if the former are not available. If the latter are used, place some old potting soil on the borders to plant the Endive in, so as not to injure any fruit tree roots that may be near the surface. The Endive may then be blanched by placing a 6-inch pot over each plant, first carefully folding the outer leaves. Plants in frames coming to maturity should be kept clear of dead leaves and loosely tied up to assist blanching. If watering is necessary, do this in the morning on a bright, windy day if possible, so that the plants become dry before night.

Globe Artichokes.—It is wise to provide young plants if fine heads are desired; now is a good time to dig up some strong suckers from the sides of the old plants, and place them in 8-inch pots. When finished give a good watering, and place them in a frame where they may receive plenty of air and yet be protected from severe frosts. The plants in the bed should have all rubbish cleared away from them, and a good dressing of half-decayed manure placed round them. In the event of sharp frosts cover them with Bracken or long litter, removing these when the weather becomes warmer.

Jerusalem Artichokes.—The stems of Artichokes may be cut down, and sufficient for present use be dug up and stored in sand. Use the largest and best shaped tubers, and save the small ones for planting next season. The white variety is much superior in every respect to the old purple-skinned Artichoke.

Asparagus.—The stems of Asparagus will now be ripe, and should be cut close to the ground. The beds may then have a final cleaning, and during dry or frosty weather receive a good top-dressing of well-rotted manure. The winter rains will wash the nutriment down to the roots, thus benefiting the plants greatly, and assisting them to develop strong crowns for next season.

Vegetables in Store.—On wet days examine the crop of Onions, and remove for present use any specimens that are not quite sound, and turn the others over carefully, allowing as much room as possible between them. Onions quickly deteriorate if stored in a damp place, therefore the driest situation possible should be reserved for them. Examine the Potatos and remove any that are diseased or in any way faulty, at the same time picking out any that are required for seed purposes, placing these upright in shallow trays, and remove them to a light frost-proof shed. Carrots, Beets and Turnips stored in sand or soil outside should not be allowed to become too wet; place some sheets of corrugated iron over them to ward off heavy rains, or, failing this, place a good straw thatch over the heaps.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BENERS, Esq., Woolverstone Park Gardens, Ipswich.

Late Vineries.—Afford the Grapes in these vineries an even, cool, dry atmosphere. Water tanks, unless well covered over, should be emptied. No other plants should be housed in these vineries, or anything likely to create a damp atmosphere while the bunches are hanging. Use sufficient fire heat only to prevent a damp atmosphere, and admit air through the bottom and top ventilators, regulating the amount according to the weather. The bunches should be examined frequently, and have all decaying berries removed. The borders, if inside, should not be allowed to become too dry; when water is necessary, choose a fine day for watering, and keep the ventilators wide open throughout the day, with a good circulation of warmth in the pipes. Outside borders should be covered with material that will ward off rain. The night temperature should not be allowed to fall below 45° in cold weather.

This interesting Rose was introduced from China by Lord Macartney, 130 years ago, and is now one of the most striking and remarkable of all the wild types. It is figured in the *Bot. Mag.*, Tab. 1377. Mr. Bean, in *Trees and Shrubs Hardy in the British Isles*, draws attention to a cross between R. bracteata and R. laevigata—the Cherokee Rose—and it must be very fine indeed. It is the R. alba odorata of gardens, known also as the Marie Leonida Rose.

I believe Viburnum Tinus var. lucidum is by far the finest form of Laurestinus for planting in the milder parts of the country. It has glossy foliage, larger than that of the common Laurestinus, and the flowers are much larger and whiter and in finer trusses. Here it commences to flower about mid-September and continues in bloom through the winter and spring, judging from its last flowering season. I know it with pleasure flowering on a bank within view of my bedroom window, and against a background of light green Cupressus macrocarpa there could be nothing better in winter. Unfortunately it appears to be comparatively tender, and I have noticed its attractiveness only in the west. Like the common Laurestinus it is used for hedges, but except for stronger growth it appears to present no advantage for this purpose.

I cannot refrain from referring to Fuchsia Scarcity, though it is only of a common greenhouse type. Of this type, however, it must be one of the best, and it has the advantage here of being hardy enough to form a shrub as readily as F. Riccartonii or F. gracilis. It is of sturdy habit and much dwarfer than these, and conspicuous on account of its fine clusters of large flowers; the tube and sepals are crimson, the petals purplish red. The name I have from a well known Fuchsia grower, who speaks of it as a market kind, one he grows himself. If the brighter and lighter colours and greater size of the indoor Fuchsias could be combined with the habit and hardiness of the so-called hardy kinds, the result might be good for the summer and autumn brightness of shrubberies. I once made a cross or two with this object in view, but it was not the kind of work I could pursue, and the only result I got was a flower with unprecedentedly long stalk, sepals and stamens, which might well have been called The Spider. The subject of this note—now late in October—is still in great beauty.

Some time ago I was much interested to find a plant of the fine but uncommon Hawkweed—Hieracium aurantiacum—struggling in turf. More recently I have been further interested to notice its use as an ornamental border plant, and for this purpose it must be very unusual. It is, however, very effective, and nothing could be more easily grown.

The flower heads of this Hieracium attain a height of about 18 inches, and they form a showy mass of dark orange or reddish yellow. It is known as Grimm the Collier. I find it described in the *Student's Flora* as naturalised in copses of the north of England and Scotland. *R. Irwin Lynch, V.M.H.*

INDOOR PLANTS.

CAMELLIAS.

Camellias are old-established greenhouse favourites, and as subjects for the greenhouse and conservatory during the darkest days of the year they are hard to beat. They come into bloom at a time of the year when flowers are comparatively scarce, and their wax-like blossoms show up against the dark, glossy foliage in a pleasing manner.

Those who grow Camellias in pots, and favour standing them out-of-doors during the summer months will have moved them indoors to flower. Very little heat is needed for Camellias during their flowering period; in fact, the cooler the house the longer the blossoms will last, so long as frost is excluded. Camellias grown in this way will usually finish flowering by the end of December, when they should be removed to a newly started Peach-house or vinery. If a plant needs a larger pot, then will be the time to pot it. First examine the roots and act accordingly, remembering, however, that the Camellia does best if under-potted rather than over-potted. A mixture of peat and loam is used by some growers, while others prefer loam alone. I find that the plants do well in loam and peat used in equal proportions, to which is added a fairly liberal amount of silver sand and clean leaf-mould. Newly-potted Camellias should be kept in a temperature of 55° to 60° until their growth is made and flower buds are formed. During this period they should be frequently syringed and kept in a humid atmosphere.

Towards the end of April move the plants by easy transitions to a cool house or cold pit, and during the last week in May place them in a sheltered situation out of doors.

Large specimens may be grown to perfection in beds in high, span-roofed houses. Some fine specimens may be seen in the big houses at Kew. Two that are always fresh in my memory are, or were (and I hope they are still), in one of the beds in the conservatory there; they were Camellia japonica var. Kimberley, carrying vivid scarlet blooms, with a delightful centre of yellow stamens, and C. j. var. magnoliaflora—with delightful flowers of glistening pink.

Cuttings of free growing varieties will usually strike freely if taken when the wood is nearly ripe, towards the close of the growing season; inserted in pots of sandy peat and plunged in bottom heat, they will root in five or six weeks.

A few outstanding sorts may here be mentioned: Camellia reticulata, often termed the Queen of Camellias, is a beautiful form carrying large semi-double flowers of bright rosy-pink colour, with large golden anthers; C. alba-plena, imbricated, and C. noblissima, paeony-flowered, are two of the best white varieties; eximia is a fine form of crimson-scarlet; C. Donkelaarii, with light red, semi double flowers, and golden stamens, is much favoured for furnishing cut blooms; imbricata produces beautiful crimson flowers that are delicately imbricated; Marchioness of Exeter is an old favourite, its large flowers of fine rose-colour being very striking; Mathioliana is a fiery red, imbricated variety that seems to be somewhat rare; C. M. Hovey and C. H. Hovey, the former of vivid crimson-scarlet and the latter with deep crimson flowers, are two fine sorts; Chandleri elegans is a great favourite among lovers of Camellias, its semi-double blooms being of large size and light-rose in colour.

Camellias are becoming more and more popular for outdoor planting, but it is only in the warmer parts of this country that they will do really well in the open. Plants grown out-of-doors bloom in the early spring, and the flowers are liable to be injured by frost and wet. *H. W. Stenning, Ebrington Hall Gardens, Gloucester.*

THE BULB GARDEN.

MAY-FLOWERING COTTAGE TULIPS.

Under this heading may be included Dutch breeders, some of which are very like Darwin Tulips. This section of late Tulips is as valuable a one as the Darwin section, and by many the flowers are preferred, as they are—or some of them are—less stiff and more gracefully formed. In one respect they are inferior to Darwins, namely for pot culture. The stiff-stalked Darwins are quite good for pots, provided one does not object to their long stems. The ideal position for them is on the ground level. I should say that placed on the floor of one of the old-fashioned conservatories, with suitable foliage plants to hide the pots, they would be very effective. One often sees Cottage varieties exhibited at the early spring meetings of the R.H.S., but they nearly always look weak and rather unhappy; their flower stalks are not stiff enough to withstand the heat necessary to flower them early, and I think the best of the Dutch forcing varieties are much to be preferred, such, for instance, as the grand old Prince of Austria, Keizerskroon, Ophir d'Or, Lady Boreel and Couleur Cardinal.

I give the best varieties of this Cottage section—taken alphabetically:—

Bacchus: A very handsome Dutch breeder; flowers large and well formed, colour richest purple, outer petals having a "bloom" like a ripe Plum; height 20 in.

Bouton d'Or: Cup-shaped, very bright rich yellow, strong, stiff stalk, very useful as a cut flower, 20 in. This variety must be well grown to be seen at its best, though the small flowers are equally valuable for cutting.

Dom Pedro: Another of the breeders; a fine large flower, coffee-brown, shaded maroon, very sweetly scented; 22 in.

Faerie Queen: Deep rosy heliotrope, pale yellow edges to petals; a large firm flower; better for cutting than for beds or borders.

Gesneriana lutea: Beautiful clear yellow; fine form; 20 in.

Gesneriana major (spatulata): Large bold flower, deep glowing crimson-scarlet. One of the finest late Tulips in existence; makes a most telling effect when planted in bold groups. A long-lasting flower; 23 in.

Inglescombe Pink: A fine large flower, pale rose, shaded salmon; young blooms have a distinct buff tint; very distinct; 24 in.

Inglescombe Yellow: A large, perfectly formed cup-shaped bloom, of wonderful lasting quality, very late, one of the last to bloom; 20 in.

Jaune d'Oeuf (Sunrise): Golden yellow, outside petals shaded apricot, distinct and attractive, but flowers are rather easily spoilt by bad weather.

John Ruskin: A very long flower, yellow, shot rose, base yellow and green; a very attractive flower, but rather inclined to "break"; 18 in.

La Merveille: A very lovely variety, colour soft salmon shot with vermilion, most difficult to describe; a long flower with an elegant

NEW HYBRID ORCHIDS.

Digitized by Google

"waist," like Picotee and Mrs. Moon; delightfully scented; 20 in.

Mrs. Moon: A stately Tulip, petals long and pointed, slightly reflexed, rich golden yellow and of fine substance; very late; height 26 inches.

Orange King: Flowers long, bright orange shot with pink on the outside; very sweetly scented, reminding one of a Maréchal Neil Rose; 24 in.

Parrot Tulips: A quaintly beautiful race, with serrated petals and gaudy colouring; unfortunately rather uncertain as to flowering, sometimes every bulb will flower, at other times half or more will be blind.

Picotee: A charming Tulip, the flowers are long and pointed with a graceful "waist"; white with narrow margin of carmine, with age the whole bloom becomes more or less flushed with carmine; a beauty for cutting; 18 in.

Purple King (Breeder): A rare variety, very like a Darwin; flower large and well formed, a beautiful old wine purple; strong grower; 25 in. Years ago I discovered this as a rogue, and after growing it for a year or two discovered "Bacchus" among it, so obtained two good things quite by chance. It is very slow to increase, like several of the best purples—hence its scarcity.

DISCARDED LIST.

Parisian White: Not a very good plant. Golden Crown: A showy Tulip, but very fleeting, dropping its petals easily, and when fully out is rather a coarse-looking flower. Inglescombe Scarlet: A lovely flower, but very thin and does not last well. Walter T. Ware: A gorgeous yellow when well grown, but such a slow propagator that it is useless to a trade grower. T. retroflexa: A beautiful and distinct flower, but a poor grower, and not so good as T. retroflexa superba. Flame: A fine variety, but greatly given to "breaking." Louis XIV.: A huge and glorious flower when seen at its best, but the whole of my stock "broke," so it was cast out! Biscuit (Clio, Bronze Queen, Sensation, or Duc d'Orleans): A distinct and attractive flower, when not injured by weather—which happened so often with me that it found a resting place in the sand pit, where many things go that are not quite up to the mark!

Gesneriana ixiodes: A pretty and very distinct flower, but too slow in increase. Glare of the Garden: Too short in the stalk to cut. Elegans alba: Also too slow; it would take a man a lifetime to obtain a stock, and Picotee is quite as attractive. Isabella: Too quickly becomes flushed all over the bloom and loses its beauty. Parisian Yellow: Not wanted with Gesneriana lutea and Mrs. Moon. Elegans: Rather small flower, weak stalk, and given to "breaking."

There are several good varieties which I have not mentioned, but they are at present very scarce, and consequently expensive, and I think the list given should supply the wants of all but the keenest growers who are on the look-out, like the men of Athens, for something new. *J. Duncan Pearson, Lowdham, Nottinghamshire.*

DIERAMA PULCHERRIMA.

DIERAMA PULCHERRIMA is a graceful, late-flowering, bulbous plant, with pendant, rosy-purple, bell-shaped flowers, 1½ inch long. These are of much substance, and remain in good condition over a period of from four to six weeks.

The beautiful flowers are borne on slender, silvery scapes, 4 feet long, delicate in appearance, but tough and wiry. Like the Sparaxis, in which genus it was at one time included, Dierama pulcherrima thrives best in a warm and well-drained, sunny position. Unlike the Sparaxis, however, it is impatient of removal, and should be planted somewhat thinly where it may remain undisturbed. Dierama pulcherrima atropurpurea is a form with darker-coloured flowers than the type, and D. p. alba is a desirable white-flowered variety. *Fred W. Jeffery, Dalserf, Lanarkshire.*

THE ALPINE GARDEN.

GENTIANA SINO-ORNATA.

I ENCLOSE a photograph of Gentiana sino-ornata growing in my garden at Glendevon, Perthshire. This photograph was taken six weeks later than that of Gentiana Farreri, which you published on p. 185, September 29. You will see (Fig. 95) that Gentiana sino-ornata flowers very freely with me; it increases very quickly, but being so late in coming into flower sets very little seed, and I find the best way to propagate it is by division in the spring. *A. H.*

RAOULIA AUSTRALIS.

OF the numerous Raoulias known to botanists there is only one which has as yet found its way into many gardens, and it must be said that its charms should give it a ready passport for admission to even the choicest collection of the flowers we know as alpines. Raoulia australis deserves a spot in the rock garden where carpeting plants are required for covering the ground under other subjects. For this purpose it is exquisite, but it has beauties of its own which entitle it to high favour. It is not a plant for strong, rich, heavy soil, in which it is unhappy even should it live, which is not at all likely in severe winter conditions. It seems to creep closely to the soil, which it covers with a multitude of little silvery leaves, starred in due season with white flowers, reminding one of those which adorn some of the Helichrysums. To give it a fair chance this Raoulia ought to be planted on a moraine or a stretch or pocket of light loam, sand and grit, in a sunny position. It delights in the dry moraine. With a plant so free in spreading (although it is not too aggressive) it seems needless to say anything about propagation, as a small piece taken from a plant and put in sandy compost will root very readily.

With regard to its hardiness one must speak with some reserve. It is, I believe, fairly hardy, but in exceptional winters may suffer badly in certain districts where spring frosts coming after a wet and open winter are rife. I have lost good plants which had survived unscathed for a period of years; and I think the winter of 1919-20 was about the worst in my experience for plants such as this. A few of the New Zealand and Tasmanian plants, of which the Raoulia is one, appear to suffer from such climatic conditions to an exceptional degree.

HELONIOPSIS GRANDIFLORA.

ACCORDING to the *Index Kewensis* this plant is referred to H. breviscapa, but it appears to be a better form of that species and is a desirable plant for the rock garden. I had it some years ago and cultivated it successfully for a considerable time in a low, moist position at the base of a rockery. Here it flowered well, but did not increase so rapidly as I would have desired. It was a plant which appeared to suffer much from drought, and I lost it when from home one very dry season, when other plants also succumbed from lack of moisture. In my opinion it likes a shady place with plenty of moisture during spring, summer, and autumn, and had I to cultivate it again I should prefer to give it bog treatment. It is quite a neat and distinct little plant with good leaves and short, stout spikes of rose-coloured flowers. It appears always scarce in commerce, and this is generally a sign that it is difficult to grow, as the enterprise of our nurserymen is so great that any accommodating plant soon becomes lower in price. This does not seem to be the case with Heloniopsis grandiflora. It is a native of Japan. *S. Arnott.*

THE ROSE GARDEN.

FRAGRANT ROSES.

THE common Moss Rose has a most pleasing odour and the shape of the flower is very fascinating. The Cabbage or Provence Rose, which was introduced about 1596 and is still favoured by many as a very choice Rose and one that every garden should contain, is delightfully perfumed. The Noisette Maréchal Neil, an old variety that requires a little protection, will produce a crop of well-shaped flowers of lasting properties, exquisite in outline, and with pleasing fragrance. Many Roses of rich and varied colours are lacking in perfume, but there are some gloriously coloured varieties that have a delicious scent.

Many Hybrid Perpetual varieties have strong perfume, including Hugh Dickson, Mrs. John Laing, La France, Louis Van Houtte, Horace Vernet, Ulrich Brunner, and Chas Lefebvre.

Many H.T. varieties may be selected for their fragrance, and the plants are, as a rule, in bloom for a long period. General McArthur is a variety that possesses the true Attar of Rose perfume; its colour is dark, the growth free and the plant is always in full flower. Richmond is a fine dark Rose with a pleasing odour. Gorgeous, of orange-yellow colour, veined and flushed with deep reddish copper, is a splendid Rose for pot cultivation or bedding and one with a perfume that is most pleasant. Golden Emblem is a very fragrant variety. The growth of this deep yellow variety is strong, the flowers large, the flowering period lasting and the perfume unsurpassed, making it an ideal Rose that is already a great favourite. Independence Day has all the good qualities of a bedding and decorative variety with, in addition, a pleasant perfume. The deep crimson-coloured Roses possess, as a rule, a pleasing odour. Most sorts of Tea Roses have perfume, but as these varieties require nursing and protection. I have omitted to mention them. *G. L.*

MR. KINGDON WARD'S SEVENTH EXPEDITION IN ASIA.*

No. 23.—OVER THE TARU TRA.

THERE was but one more range of mountains between us and the endless wet forests of Indo-Malaya. That day we climbed out of the Taron gorge and reached the last village—if three empty huts could be called a village—we were to see for several days. But the climb of a 1,000 feet was wasted; for on October 30, after a difficult march along the face of the mountain, buried in thick grass, we descended to cross a big stream, and had to make the climb again.

However, on October 31 we began the serious ascent of the Taru Tra, marching up the valley, but keeping well up on the flank of the range. Endless deep gullies had to be crossed, and in the course of seven hours' hard marching we covered barely four miles.

At first we were enveloped in forest, consisting largely of Oaks, Bucklandia, Michelia, Magnolia, a Schima, with creamy-white flowers; a Stamineum Rhododendron, and several species of Araliaceae. Then, coming out into the open park country, we found Pines and Alders again, with the usual tangle of shrubs. A species of Akebia, with black seeds embedded in an edible pulp, was found here. On the trees were several Orchids (Coelogyne) in flower.

As we got higher Rhododendron sino-grande reappeared in a rather squat and gnarled form, with capsules half destroyed by grubs. In the deep wooded gullies were dense thickets of a violet-flowered Strobilanthes forming big bushes 6 or 8 feet high. A few miserable species of Impatiens were also in flower. The going was bad, and I gathered unto myself numbers of forest ticks, which stabbed shrewdly, with a proboscis like a blunt fish-hook.

There were few shrubs, those which came under my notice being species of Euonymus, Ilex and Rhododendron sino-vaccinioides, the last often epiphytic, or growing on granite cliffs. The only other Rhododendron met with during the day's march was the common Irroratum type (K.W. 5474)—probably R. eriogynum.

We camped in the forest, not far above the torrent, at the lower limit of the real temperate forest. Altitude about 8,000 feet. On November 1 it rained in the night, and the temperature only fell to 43° F. We descended to the torrent bed and continued up the valley. Here the forest consisted chiefly of candelabra-like R. sino-grande and immense, moss-clad Pseudotsuga. In the gullies were thickets of shrubs, Lilium giganteum 12 feet high, and Polygonum; also bushes of sticky Strobilanthes, rather pleasantly scented, like Angelica.

As we ascended, a sprawling bush Rhododendron of the Haematodes type took the stage—the rust-red felt on the underleaf was a conspicuous feature. There was also a small epiphytic yellow-flowered species of the Boothii type. This was actually in flower!

Crossing the stream, we turned up a side valley, choked with bushes, amongst which Rhododendrons were conspicuous. But there was also a terrible lot of Bamboo, and the higher we climbed the more this Bamboo predominated, and the less chance there was for anything else. Nothing would grow under its shadow, except a few small Rhododendrons of the Sanguineum and Haematodes type. On the rocks were small bushes of a species like R. glaucum, with a poisonous smell; and in the open a few miserable plants of Primula serratifolia lingered on in flower. A species of Akebia dangled big purple Potatos in our faces as we forced our way through the thickets; but the pulp of this species was not nearly so tasty as that we had found in the morning.

It began to rain heavily, and before we reached a draughty shelter-hole under a big rock we were wet through. The altitude was not more than 9,000 feet, but it was quite chilly, and the outlook, with the mist swirling round the cliffs, was depressing. The temperature had fallen to 37° by early morning, but the weather looked brighter. However, we were soon drenched forcing our way through the dense Bamboo brake to the head of the valley. We were now faced with a lofty granite wall, which looked absolutely sheer; and it certainly was abominably steep. We mounted by a scree. There were practically no Rhododendrons here, only Bamboo, and, in the open, thickets of tall herbs, such as Polygonum, Rodgersia, Astilbe and Umbelliferae, with tangles of Rubus, Viburnum and dwarf Juniper; but mostly Bamboo.

It was not encouraging.

At last we reached the knife-edge summit and had a clear view westwards over the wide wet hills and vales of Indo-Malaya, soft and green in the mist. It was snowing, but the sun came out and shone on the wads and strips of cloud below. We were now 4,964 feet above the Mekong, or nearly 11,000 feet above sea level.

But we were in a sea of Bamboo, and there seemed to be hardly anything else on this barren granite except a small Saluenense Rhododendron; and most of the capsules of that had aborted. (K.W. 5434). A little lower down, however, we came to open alpine slopes, covered with bushes of a Trichocladum species. (K.W. 5489).

The descent now followed a well-wooded ridge, and Rhododendrons became more numerous, if less accessible. But it was already clear that we had seen the best of them; another thousand feet descent into that all-devouring jungle, and hardly another plant should we see, except a few hopelessly soft Irroratums and Stamineums. In the middle of the afternoon we reached the valley, and followed the stream which clattered down a steep stony gulch, lined with forest. Nothing much was visible. I picked up the milk-white corollas of an epiphytic Maddenii Rhododendron, but it was a couple of days before I could secure a plant; it was just coming into bloom and was deliciously fragrant, and about as hardy as a hot-house Orchid.

We camped under a rock, in the gloomy forest which was presently illuminated by a heavy thunderstorm; but the storm cleared the air, and when we started again next morning, the weather looked far more promising.

We continued to descend, and there was no disguising the fact that the forest was now tropical. The big Musa plants, the tree Ferns, Figs, Aroids, Melastomaceae, and Palms told us that. In the afternoon we reached a village and halted for the night. On November 4 we resumed the march, crossing a river and so over the shoulder of a spur, from the top of which we saw the Taron again, now galloping up from the south. Like the Yangtze, it forms a loop here, and must be crossed twice; or rather, we did not cross it a second time, but followed it westward for a day. The jungle here was hot and sticky, for we were barely 4,000 feet above sea level. There were climbing Palms and huge Bamboos, and lovely Englehardtia trees, and many Leguminosae with queer pods—conspicuously Entada, Bauhinia, and Cassia species. I found a form of Rhododendron indicum with bright carmine flowers, and there were plenty of Orchids on the trees, big Screw Pines, and a great variety of trees unknown to me. After crossing a river called the Tazu-wang, by a cane suspension bridge, we looked back and saw the high mountains for the last time—the glorious Rhododendron-covered mountains of the frontier. Ahead lay the jungle.

We marched for a day in the steamy valley of the Taron, and I learnt that we were now only twelve marches from Fort Hertz. Then in quick succession we crossed two big tributaries, still in the dense jungle. I found a magnificent Clematis in flower here, with wine-coloured petals and cream stamens.

The Taron was fairly thickly populated, to my great surprise, and I had no difficulty in getting porters and supplies; it was necessary to lay in stocks, because a considerable stretch of almost uninhabited country lay between us and the plains of Hkamti Long.

It was sad to have crossed the mountains so quickly—as it seemed now; though at the time it appeared a toil. We left Chamutong on the Salween, on October 20, and by November 3 had crossed the Gompa La, the Taron, and the Taru Tra, and were marching through the jungles of the lower Taron, with no more serious mountain ranges ahead of us, only hills, hills, hills, and rivers, endless rivers; and everywhere the hot, sticky jungle. Even in November the heat in these deep valleys was oppressive. Rain fell nearly every day, though this was the fine weather season! But the rainfall here exceeds 120 inches a year, and though the bulk of it falls during the six summer months, there is plenty left for the winter!

F. Kingdon Ward.

* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, 29, 1921; January 7, 21, March 11, 25, April 8, 22, May 6, 20, June 3, 17, July 1, 15, 22, August 5, 26, September 9, 23, October 7, 21, November 4, 18, December 2, 16, 30, 1922; January 13, 27, February 10, 24, March 10, 24, April 7, 21, May 5, June 2, 23, July 7, 21, August 18, September 1, 29, and October 20, 1923.

PLANTS NEW OR NOTEWORTHY.

SYMPLOCOS PANICULATA.*

THE gardens of New England are denied the wealth of hardy, broad-leaved evergreen plants which thrive exceedingly in Old England, and the variety of plants that can be grown out of doors here is much less, but there are compensations. Plants that do thrive grow more rapidly, flower more freely and fruit much more profusely than they do on the other side of the Atlantic Ocean.

Nothing we have growing in the Arnold Arboretum impresses a gardener from Great Britain more forcibly than the wealth of fruits developed on the shrubs and trees. Such visitors find that many old and familiar plants possess a world of beauty hitherto quite unknown to them, and certain it is that the perfectly hardy, woody plants put forth their ornamental qualities to the maximum in the climate of New England.

Another interesting fact is that quite a number of plants considered not fully hardy in England flourish here quite unprotected, the much more severe winters notwithstanding. An excellent example of this is Symplocos paniculata, the Sapphire-berry, more generally known as S. crataegoides. In the mild climate of Great Britain this is usually regarded as a tender plant, whereas in the rigorous climate of Massachusetts it is perfectly hardy. The explanation of this is to be sought for in the greater summer-heat enjoyed here, which properly ripens the wood. In the Arnold Arboretum this plant is 18 ft. tall and 15 ft through, and has been growing in a fully exposed situation since 1880. Not only is it

* Wallich, ex D. *Prodr. Fl. Nepal.*, 145 (pro. synon.) (1825).

Digitized by Google

quite unaffected by winter's cold, but each spring it flowers profusely, and each autumn fruits abundantly.

The Sapphire-berry is a shapely, much-branched bush or tree-like shrub with hard wood clothed with pale grey fibrous bark, and has rigid, twiggy branchlets. The leaves vary greatly in size and shape, and are more or less ovate or elliptic to obovate, shortly stalked, from two to four inches long and one to two inches broad, finely serrated on the margin, and often with a short, acuminate apex; the veins are deeply impressed above and raised below, and the underside of the leaf is more or less hairy. The flowers, produced at the end of May or early June, are white or cream-coloured with a conspicuous mass of stamens; they are borne many together in a short, erect, paniculate inflorescence at the end of the current season's leafy shoot.

yolk Shrub," as it is called in Korea. It was introduced into cultivation in 1875 by Thomas Hogg, who sent it from Japan to the Parsons' Nursery at Flushing, Long Island, New York, and the plants growing in the Arnold Arboretum are of the original stock. In flower the Sapphire-berry, with its profuse, erect, paniculate masses of star-like blossoms, is a lovely plant, and its lustrous blue fruit is as handsome as the gem from which I have coined a common name for general usage. The foliage is good, and the plant is not attacked by any pest, although starlings have an uncanny fondness for the ripe fruit. *E. H. Wilson, Arnold Arboretum.*

ALOCASIA MACRORHIZA.

The seeds of this plant were collected by Mr. Reginald Farrer, in China, in 1919, and sent home under "No. 1445, Alocasia Species." The seedlings were planted in the open in May, 1922, and some protection was given them last winter. The large leaf, 3 ft. 7 in. long and 2 ft. 9 in. across at the end of a 6 ft. stalk, is a fine object in itself, and is known as the Elephant Ear owing to its resemblance to the ear of that animal. Flowers were produced on several of the plants late this summer; they are like the spathes of a large Arum, purple and yellow on the outside and butter yellow inside.

Alocasia is a plant of the tropics, and though this species was found at an altitude of 6,000 feet on the Burmo-Chinese frontier, the climate of its home must be a fairly warm one.

Farrer's note on the plant is: "Huge and very handsome Aroid foliage, but not very likely to be hardy, though I got this seed off specimens on a high, bare slope about 6,000 feet. It need not be either despised or deplored."

This Alocasia (Fig. 97, p. 265) was recognised by Mr. E. H. Wilson as A. macrorhiza (or macrolisa?) when he saw it growing in the garden here last summer. *Kenneth McDouall, Logan, Scotland.*

SOIL SOURNESS.

Among the most stimulating and useful of the discussions held in the Botanical Section during the recent meeting of the British Association in Liverpool was one on soil sourness. This is indeed not surprising, since, in addition to its theoretical interest to the botanist and the chemist, the subject presents many problems of great importance to the farmer and, albeit, less urgently owing to smaller scale and more intensive culture, to the gardener also.

Attention was directed to the fact that soil "sourness" and soil "acidity" are not interchangeable terms. The conditions described do not necessarily occur together, although some degree of acidity is commonly a feature of "sour" soils.

FIG. 96.—FRUITING BRANCH OF THE SAPPHIRE BERRY, SYMPLOCOS PANICULATA.

The fruit of Symplocos paniculata (Fig. 96), which ripens in September, is an ovoid drupe about one-third of an inch long, of a lovely deep sapphire-blue colour, and is borne erect. The plant is really polygamo-dioecious, and so it happens that while some plants fruit abundantly others fruit very sparingly.

This uncommon plant in gardens belongs to a genus rich in species and widely distributed over the warmer parts of the world, very few of which are in cultivation. Nearly all are evergreen, but S. paniculata has deciduous leaves, and is the only member of the genus that is hardy in the Arnold Arboretum. It has a remarkably wide distribution in eastern Asia, being found wild from the north-west Himalayas eastward through China, Korea, Formosa and Japan. The plant is partial to scrub-clad rocky slopes, and is fond of full exposure, though frequently it grows on the edge of woods and in glades. It varies considerably in size of foliage and flowers, but the gradations are so even and so complete that it is impossible to distinguish any really distinct forms.

When dried in the sun the leaves always turn yellow, hence the name of "Egg-

In practice, soil "sourness" is recognised by the characteristic failure of certain crops; by the dominance of certain weeds, e.g., Field Spurrey and Sheep's Sorrel; by the prevalence of certain diseases, notably Finger and Toe of Cruciferous crops; and, lastly, by the rectification of all these conditions that immediately follow an application of lime or chalk to the soil.

Now the cause of "sourness" is not acidity or hydrogen-ion concentration, since this may be high when "sourness," as above defined, is absent.

The following features are associated by the soil chemist with soils of this class:—(1) Acidity on high hydrogen-ion concentration; (2) a high power for absorbing lime; (3) characteristic ratios expressing the proportions of the various soil bases present—calcium, magnesium, sodium and potassium on the one hand with the so-called weak bases—aluminia, iron, manganese, etc., on the other.

That the problem is a very complex one is indicated by the fact that, although the peculiarities just cited are invariably found in "sour" soils, cases are not lacking of

Digitized by Google

certain soils, rich in organic matter, which possess these characteristics without the corresponding phenomena of "sourness." While the practical grower associates the problems arising from soil sourness more especially with the failure of certain crops, the plant ecologist finds that the prevalence of certain species in the field is a reliable indication of sourness, although he is puzzled at present to know whether the characteristic healthy type of vegetation so frequently found on these soils is correlated directly with the scarcity of lime salts or with the acidity and deficiency of oxygen usually coupled with this scarcity of calcium.

Much experimental work bearing directly or indirectly on the problem is in progress, both in this country and in the United States. More especially may results of special interest be looked for from the three following lines of research:—(1) The significance of acidity (hydrogen-ion concentration) in relation to plant growth; (2) the effect of variation in the proportions of the various soil bases, more especially calcium, magnesium, sodium, potassium and aluminia; and, closely associated with the latter, (3) the real significance of the so-called lime-shy or calcifuge habit in certain groups of plants.

Bearing on the first of these, Dr. E. F. Salisbury contributed a paper at Liverpool in which the results of numerous observations on the degree of soil acidity associated in nature with the distribution of particular plant species were expressed as curves. It was suggested that certain species, e.g., the Bracken, has a natural distribution closely associated with the degree of soil acidity, a well-marked "optimum" being recognisable in the curves. On the other hand, discussion elicited the fact that no experimental data were available to support the view that the soil reaction behaved as a critical factor.

Both in this country and in the United States data are rapidly accumulating recording the association of particular species with varying degrees of soil acidity, and experimental work is in progress to test the existence or not of critical degrees of acidity for individual species.

At present no sure conclusions can be drawn, and it must not be forgotten that many difficulties of interpretation arise. For example, the presence of certain plants, e.g., Sheep's Sorrel is often regarded as an indication of sourness. Experimentally, it is known that Sorrel will grow quite well on calcareous soils, and in general it must be recognised that a plant may grow well on "sour" soil, not because the condition is specially favourable to it, but because, being relatively tolerant of sourness, it flourishes owing to lack of effective competition.

Similarly, a plant species may be absent from natural vegetation, not because it cannot tolerate the soil conditions, but because its toleration is less than that of any of its competitors.

In another field of research, a group of workers attaches great importance to what may be called the "basic ratio" of the soil. It was pointed out by Dr. Comber that the cause of sourness is not merely the ratio of calcium to other bases (e.g., potassium and sodium), since the addition of neutral calcium salts does not reduce the sourness, and the addition of potassium and sodium salts does not enhance it.

In the rather special case of Heath plants, which so commonly form the natural vegetation on sour soils, it is held by certain workers that the important basic ratio in the soil is the proportion of sodium, potassium and magnesium, to calcium, on what is termed the

$$\frac{K + Na + Mg}{Ca}$$

There is also some evidence that the ratio of basic lime to weak bases, especially aluminia, may be a fundamental cause of sourness—a view which fits in well with the known toxicity of aluminium under certain conditions.—*M. C. R.*

THE RELATIONS BETWEEN HORTICULTURE AND PHYTO-PATHOLOGY.*

IT is certain that in the future growers will demand seeds free from disease. The more natural way seems to be that florists and vegetable growers should use sterilised seed themselves before they are made to do so. It is an astonishing fact that seed disinfecting is not already more popular. One of the reasons is that the methods of destroying seed parasites have not been worked out carefully. Most of the larger experiments have been made with agricultural seeds; with the vegetable and flower seeds we are far behind. It is true that several treatments which control the dissemination of seed diseases have been worked out by phyto-pathologists and agriculturists. I need only mention to you the copper treatment for bunt of Wheat, the formalin method for loose smut of Oats. More up to date are the experiments with compounds of chlor-phenol mercury, the uspulun-fusuriol and germisan group being popular in Germany. Even for parasites that live inside the seed-coat, the hot water treatment solved the problem, as i.e., for the loose smut of Barley. On the other hand, several methods are recommended by chemical industries, whose representatives are often obliged to make hypothetical statements of the results. There is a lack of faith, with or without reason. Here there is a large field for phyto-pathology, which surely will be ploughed with success. How far advanced are we with regard to horticultural seed?

The life history of some of the fungous parasites of vegetable seeds is well known. The anthracnose of Beans and Peas, caused by Colletotrichum Lindemuthianum and Ascochyta Pisi, form their pycnospores on the seed and their mycelium lives inside. This seed contamination gives rise to seedling infection, and later to serious attacks of the stems, leaves and pods. The leaf disease of Celery, Septoria Apii, develops its spores on the seed and the mycelium in the seed-coat. We find it mentioned that the Cucumber seeds carry the spores of Corynespora. But no scientific worker has yet brought any real proof in support of this supposition. The same is probable for Colletotrichum lagenarium. The facts have not been stated, and disinfection seems superfluous before we are well aware of these facts. We find evidence of the Hollyhock rust resting in the seed, but the statements have never been made in a faultless way.

So it is with the rusts of many vegetables and flowers. We find "sayings," but no statements, that Onion seed carries the spores of the Onion smut fungus, Urocystis cepulae. Orders against seed importation are issued. It seems very improbable that the smut spores formed at the base of the bulbs of young plants should ever reach the seed and stick to it. But there is a necessity to solve this problem, in order to avoid unnecessary trouble for seed growers. Phyto-pathologists should prove in a faultless way whether the seed carries smut or not. We should be well aware that this is not a task easily solved. Smut spores of Onions do not germinate readily; it will be a hard task to grow them in artificial culture, and only such cultivation of the fungus from the seed will solve the matter. The fungus of the Tomato canker, Diplodina lycopersici, produces anthracnose of the fruit, and is likely to attack the seed. However, we must state our ignorance.

The investigators of the genetics of the genus Antirrhinum or "Snapdragon" are well aware of a fungus trouble, which is a typical anthracnose of the stem, that kills the plant either in its seedling stages; or destroys the foot of the stem, so that the plant dies out. It is Phoma antirrhini which causes these losses.

* Abstracted from a paper on "The Relations Between Horticulture and Phyto-pathology," read by Prof. Johanna Westerdijk, Baarn, Holland, at the International Horticultural Congress, Amsterdam, Sept, 1923.

There is a possibility of the fungus living in the soil, as sometimes we see the disease reappear in the same places in hothouses; but, on the other hand, the fungi that produce pycnidia like the Phoma generally live on seeds, so I suppose we must class it with the Septoria, the leaf disease of the Celery, and try to look for control through the seed.

The case, probably, is somewhat different with the Phoma disease of the Phloxes, also a pest of some of the newest varieties. It is characterised by the same stem anthracnose as with the Snapdragon, and the same symptoms of the young, succulent shoots, which are so easily affected. But the Phlox, being a perennial, is probably always reinfected from the soil or by way of pycnidia from its own roots. Seed carriage may be possible, but has less importance for the culture of this plant. The same may be said of the Lavender Phoma, well known in England, and, like the former, causing a dying-out of the stem.

I only mention several examples out of many. These show that the plea for research is urgent. Nevertheless, they illustrate the great number of open questions concerning seed contamination; the fact that our seed-testing station has developed a department for mycology means that greater interest is being taken in these problems. Not only the occurrence of spores on the seed, but also the seed treatment, should be better understood. Next to a disinfecting influence, several of the toxic agencies stimulate the germination process and growth. Mercury-compounds, phenolic acids, and the more modern chlor-phenol mercury compounds are known to work in this direction. For the parasites living inside, the method of applying heat may be used. For Celery seed 48° is sufficient.

The present difficulty is that in different soils and under different conditions the results were never the same. Laboratory, greenhouse and field tests should be made on a large scale, so as to attack the question at its base. As soon as safe methods have come to our knowledge, regular disinfection of the seeds that want it may help horticulture to ensure healthy seed. Severe epidemics must disappear. Seed anthracnoses should become as rare as bunt of Wheat in countries where grain seeds are treated. The international importance of this question has, I think, hardly been realised.

Among methods of checking diseases in "sick" soil, the one the Americans have been following is the most successful and the most promising. They conquer diseases by growing immune varieties. When we consider the well-known and tested cases of immunity against fungous diseases we are obliged to admit that the most notable instances are chiefly found amongst wilt diseases, which are soil borne. American investigators have selected, with great success, types that resist wilting on the "sickest" soil possible.

Taking as an example the breeding of the Tomato, concerning resistance against Fusarium lycopersici, it must first be mentioned that wilting of Tomatos here is generally caused by Verticillium albo-atrum, but, on account of higher soil temperatures, in the U.S.A. the wilt caused by Fusarium is prevalent. The investigators selected individuals that possessed a marked resistance when grown on heavily infected soil.

The Tomato in America is in general self-fertile. Crossing with susceptible varieties seldom occurs, and so it is easy to keep the resistant strains pure. At present the U.S. possesses several strains of Tomatos that may be grown on infected soil with a very high degree of resistancy. The same has been done by Jones and his pupils with Cabbage, against the Fusarium soil disease. (F. conglutinans). After selecting resistant strains, it remains necessary to apply a certain selection throughout successive generations.

As with the Cabbage and the Tomato, resistance was bred into Watermelons, Cow-peas, Flax and Cotton. In some cases hybridisation was necessary, as with Cotton and Water-melons, in others selection was sufficient. In the case of soil parasites these resistancy experi-

Digitized by Google

ments are easily handled, because the parasite conditions than fungi exposed to wind, rain is more steady in attack under different and drought.

Breeding against soil fungi is more promising than breeding against different rust diseases, as rust resistancy depends largely on climatic conditions, and we know that in different climates or even in similar climatic conditions different strains of a parasite may prevail. This fact has not yet been stated in regard to parasites, but it may at any time complicate our trials and experiments.

Not many attempts have been made in Europe to breed resistancy against soil fungi. Asters, Lathyrus, Tomatos, and Cucumbers are in want of such attempts. There is need for securing strains of Tomatos fit for continuous cultivation under glass in the same houses. Meanwhile one Tomato variety after another is passing away, and nobody fully understands why. If it be true that Verticillium, our most common soil parasite, is such an omnivorous species, it is questionable whether breeding for resistancy in Western Europe will be so successful as in the case of Fusarium in America. We know that the more specialised the parasite, the smaller the chance that we may find or breed resistant forms of our plants. This statement, however, should not discourage. Other unknown factors may favour such selective work.

(To be continued.)

DEVELOPMENT OF THE DAHLIA.*

(Concluded from page 251.)

The Paeony-flowered and Decorative Dahlias.

About 1900, Mr. Hornsveld, a Dutch florist at Baarn, showed a new strain of Dahlias he had raised. The flowers were mostly half-double, and were borne on very stout, rigid stems. They were somewhat or even very irregular of outline in some cases, and hence could not at once charm the severe Dahlia critics, who were accustomed to judge flowers after a prescribed standard of qualities. Under the auspices of well known Dutch firms the new strain was repeatedly shown in England, France, Germany and elsewhere. The first reception in England was rather cool.

So high an authority as the Editor of the oldest English horticultural trade paper condemned them to death without any hesitation. "The blooms," he states in a report of a R.H.S. meeting, "consist of huge, long, ragged florets in one or two rows round a yellow centre, and violate, as far as form goes, every canon both of the florist and of good taste. They are of no use for cutting, as they evidently flag quickly after being removed from the plant, and their only use appears to be to produce a vivid splash of colour in the garden; however, the exhibitor tells us they are 'selling like hot cakes,' so we suppose we shall have to endure them for some time to come."

Mr. Hornsveld, however, soon followed by others, not only in Holland, succeeded in improving the strain from year to year. The first varieties offered, Queen Wilhelmina, Queen Emma, Duke Henry, Baron de Grancy, and others, were successively discarded and replaced by Princess Juliana, which has proved an ideal white in every respect, and many others which have been and still are the glory of our autumn shows and the delight of the garden.

Meanwhile Mr. Pfitzer, of Stuttgart, had raised a similar strain of single and half-double varieties, which were offered under the name of Semi-Double Giant Dahlias, of which he published new varieties almost every season till 1910. The increasing success of this type of flower naturally led to the production of similar seedlings elsewhere, but Mr. Hornsveld rightly claims to be the pioneer raiser, and it cannot be denied that he and the other Dutch growers have made this section what it is now.

The new strain proved to have excellent qualities for decorative purposes and not to cause disappointment in the garden. The flowers are not hidden in the foliage, as with so many Cactus varieties, and the stems are strong and upright. Modern taste did not require flowers manufactured after a theoretical scheme dictated by some florist's flower maniac, but graceful flowers, freely produced and naturally growing without special care or management, and the newer Paeony Dahlias answered to such expectations.

It has always been somewhat difficult to exactly define the qualities of the flowers of this strain, and this difficulty was increased because numbers of varieties were not semi-double but full, and originally were distinguished as "Decorative Dahlias" from the former. In later years both types have become so much mixed up that it is almost impossible to distinguish them.

This, however, is a matter of secondary importance. The chief point is that the Paeony and Decorative Dahlias are now universally recognised as the leading varieties for garden and decorative purposes. Holland may be proud of this result. The seedlings of Hornsveld, Kroon, Ballego,

FIG. 97.—ALOCASIA MACRORHIZA (SEE P. 263.)

Wouters, Kriest, Carlee, Vianen, van Waveren, Glasbergen, Ludwig, Eveleens, Maarse and others of my fellow countrymen have spread everywhere, and are to be found in Dahlia collections in all parts of the world. These varieties have obtained certificates of merit after examination in trial grounds, and hence have proved to be real acquisitions of merit.

In addition to these Paeony and Decorative Dahlias several forms were raised of Cactus shape, but having stems as solid and rigid as those of the former. Such varieties are grouped as Garden Cactus Dahlias

The success of the Dutch garden varieties excited the production of similar varieties elsewhere. The United States at once recognised the important qualities of this section, and the novelties raised there mostly belong to the same group. More than one Dahlia society has been formed there by the numerous amateurs in the States, who have devoted themselves to the Dahlia cult with all the energy which Americans display, not only in matters of business, but also where their hobbies are concerned.

The Collerette Dahlias.

The same principle of producing useful garden plants, which prevailed in the raising of the Paeony and Decorative varieties, led to the improvement of the Collerette Dahlias in Holland. The first Collerette varieties came from France in 1900. Two seedlings raised at the Lyon City Park had single flowers of a dark colour with a row of small white florets round the golden central disk of the flower, which suggested a sort of collar; hence the name. The two varieties were followed by others, but all had very thin, drooping stems, and not until the Dutch and other growers succeeded in obtaining a strain with wiry upright stems were the Collerettes generally appreciated and used. The Dutch strain is distinguished by musical names, and Fuga received the highest honours in Holland.

New Starry Single Dahlias.

Another French strain has recently been offered for the first time. The type was discovered in a French amateur's garden, and it was Monsieur Martin, a nurseryman at Digoin, who succeeded in developing this type into the strain which has since been offered under the name of Etoile Digoinaise. The flowers are single, very much starry shaped, and the coloured florets are more or less tubular shaped at the top, which gives a novel appearance to the flower. Several varieties have gained awards of merit at Paris. They have not existed long enough for us to know whether they will maintain a position in future.

The Clematis-Flowered Dahlias.

This review of the modern Dahlias would be incomplete without mentioning a new type produced by the Dutch grower, Mr. Wouters, and somewhat suggesting the old Anemone-flowered forms. His seedlings, which have been offered under the names of Ada Finch (white) and Clematis (violet), more remind one of a Clematis flower than of anything else. The shape of the flower is absolutely distinct from any known older variety, and both sorts are very free bloomers, and hence good garden plants.

Conclusion.

The Dutch Dahlia Society deserves high credit for the excellent way it has advertised the Dutch Dahlias in other lands. Thanks to their artistic arrangement under the able management of Mr. Ballege, the standard varieties, as well as the new conquests, were shown to their best advantage in the Horticultural Hall in London, at the Société Nationale d'Horticulture de France, and at Antwerp. Everywhere those exhibits have been greatly admired, and even the critic of the trade paper referred to above became enthusiastic in his praise. Certainly those decorative sorts produce vivid splashes of colour in the garden—for which he seemed to reproach them—as every Dahlia ought to do, but does not. The future is for those varieties which give satisfaction in the garden. The new Star type raised in England has already proved its immense value in this respect.

In Holland no new Dahlia can obtain a First Class Certificate unless it has first gained a Certificate in a trial garden. In Germany the National Dahlia Society, still earlier, laid out Dahlia gardens in several large towns, where the garden varieties could be demonstrated at their best, and the public learn to appreciate them. These excellent ideas were followed by the R.H.S. when they arranged Dahlia trials in their garden at Wisley, and decided not to give a certificate or award for new varieties before they have proved to be free flowering and effective as garden plants. This is the only criterion, and it is the claim of the Dutch varieties, whether they belong to the Paeony, Decorative, Garden Cactus or Collerette sections, that they are real garden plants.

They are not show flowers after the ideals of the conservative florist, who used to present his blooms, without stems, on boards, in stiff rows, and, later, on wire frames in compact pyramids. Nevertheless they are the glory of our gardens, and our autumn shows, and the Amsterdam exhibition has demonstrated again how the Dutch varieties have increased the importance of the Dahlia as an object of commerce, but above all, as a flower of beauty and refinement.

* A paper read by Mr. Ernst H. Krelage before the International Horticultural Congress at Amsterdam, on September 18.

AUTUMN SOWN PEAS.

Early dishes of Peas are always highly appreciated, and any method of cultivation which will advance, by even a few days, the gathering of pods of this vegetable is of value to the grower.

On heavy clay soils autumn sowing has little chance of being successful, but on light, sandy soils, in all but exceptionally bad winters, autumn-sown seeds develop plants which are able to withstand the winter, grow away vigorously in the spring and produce pods a week or ten days ahead of any that are sown outside in the spring.

The essential factor is to produce strong, sturdy and not too large plants before mid-winter, which will withstand the adverse climatic conditions of our winter season. For this reason sowings should not be made too early or growth will become too advanced and succumb to the severe conditions. It is not easy to fix a date for sowing; seasons and other conditions vary so much that this must be determined by the judgment of the grower; a good plan, however, is to make two sowings, the first early in November and the second about ten days later. I this means it is often possible to winter at leas one sowing, whereas if a single sowing is relied on the plants might be subjected to abnormal conditions, which would unfit them for withstanding bad weather.

The seeds should be sown in well-prepared trenches in which the soil has had time to become consolidated, and they should be covered to the depth of two or three inches with a prepared compost of old potting soil. It is important that thin sowing should be practised to enable each individual plant to develop freely under natural conditions and become robust and strong; plants which have to fight for their existence under crowded conditions cannot be expected to survive the winter.

If trouble from mice is anticipated, it is a good plan to moisten the seeds and roll them in red lead before sowing. If this precaution has not been taken and trouble arises after sowing, fine coal ash steeped in paraffin and scattered over the surface of the trench is an excellent deterrent.

The plants should be supported when a few inches high by means of small, twiggy sticks, which keep them from being blown about and also act as a protection; the final staking may be done when growth becomes active in the spring.

I find the variety Pilot is the best for autumn sowing, as its hardy constitution enables it to withstand the rigours of our winter better than most other varieties. Its flavour is admittedly not equal to that of some of the marrowfat varieties, but it is not often that the flavour of very early dishes of Peas is called into question. *W. Auton.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Gardeners and the Imperial War Graves Commission.—I desire to draw the attention of your readers to the use and abuse of the title "Gardener" as applied to men working in France for the Imperial War Graves Commission. What few real gardeners are engaged will, I am sure, be glad to have public attention drawn to the official methods of making a gardener. Of some 2,000 men engaged on the work, only about one per cent. are actually gardeners, in knowledge and pre-war employment. Considering there are so many skilled gardeners unemployed I consider the cemetery work should be given to them. I was for twenty months in the employ of I.W.G.C., and began to find how scarce actual gardeners were. The "Head Gardeners" or foremen were for the most part ex-policemen, old army men, naval men, and costers, and rarely those who had earned their living as gardeners. Coming lower down there were men who had been barbers, carmen, waiters and paper boys, dignified by the title of "Gardener." Most of the men go out as "Gardeners' Assistant," and in order to get the extra 10s. weekly paid to "Gardeners" they go through a farcical gardening examination; this examination is also open to clerks in offices, who, having known the answers to questions, soon pass the test, and are "Gardeners" on the wage sheet. Investigation will show that on the I.W.G.C. "Gardener" is a title held in contempt and derision. I know many good labourers on this work who should be made gardeners, and who have knowledge and experience. I held a sub-foremanship for a time, but, disgusted with official methods, I resigned, and I was replaced by an ex-fitter by trade previous to his employment with the Commission. After my resignation I was induced to remain in my employment, but as a result of unfair treatment I had cause to make a complaint to the London office; unfortunately, however, the London office does not investigate, but simply passes complaints back to the officials, consequently I found myself being ordered to push a barrow for labourers—although a skilled gardener of twenty-three years' experience. I did not remain with the I.W.G.C. I am not the only gardener who has had a similar experience. In my opinion, the whole business is bad, and what few skilled, decent men there are, are compelled to resign. A former comrade left to go to Kew; others returned to England after only two months' service. Those who are conscientious, skilled and of good conduct stand little chance under the scheme. The whole business of the Commission needs overhauling from top to bottom, and only the best men should be employed; at present men employed under the I.W.G.C. are forbidden to write to the Press, so, on behalf of those who are skilled and honest, I write for them. It may interest your readers to know that the following wages are paid: Head foreman, £3 10s.; sub-foreman, £3; gardener, £2 10s.; labourer, £2; plus, in all cases, 30s. board allowance, one month holiday yearly with wages, and fares paid; ordinary English festival holidays, and also French ones are allowed, and, of course, for about fifty days in the winter no work can be done. There are many things requiring to be made public concerning the Commission, but I particularly wish to draw attention to a grievance that is essentially one for gardeners *J. W. Martin, Lavethan, Blisland, Bodmin, Cornwall.*

Pea Senator.—On April 1 I sowed a row of Pea Senator. The plants grew very well, and on June 30 I gathered well-filled pods with nine or ten Peas in a pod. By July 7 the crop had been gathered. I usually pull up the haulm to make room for Broccoli, which do well with me between rows of Peas. However, this year I did not remove the plants and they flowered again in late August, and this week (October 16) I am again pulling good pods of well-filled Peas from the old row. Other Peas were sown on the same plot on the same date, namely, Daisy and Improved Queen, but these dried off. The land grew Potatos last year, but was given no manure this year. I shall grow the variety Senator again and leave it, but give it better treatment, as it may give me a few good dishes of late Peas. My garden is very cold, and to sow late Peas is practically useless. I should very much like the opinion of others on this matter. *G. H. S.*

[*G. H. S.* may not have a similar experience for 20 years. The Pea Senator is at least two weeks earlier than Daisy or Improved Queen. The haulm is also more slender; the pods are narrower and not so fleshy; the plant is more branching, and the pods more numerous and produced all over the plant, right up to the top. It has also a better constitution, is not so liable to mildew, and is not so easily damaged by unfavourable seasons. It is a poor man's Pea as regards its cropping qualities and fit for a king as regards flavour and appearance. It has only one fault, the skin of the seed sometimes splits in the pods that are being saved for seed. Daisy and Queen are both Peas of extra fine quality and appearance, but the plant of each is very luxuriant in growth and needs favourable conditions to develop it to perfection. A drought or a cold rainy spell would injure the plants badly. Senator would far more easily recover, as it has done in this case, and nine times out of ten would give the largest crop of shelled Peas.—Eds.]

Holland Park Hall Show.—Allow me to thank you for your able leader in the *Gard. Chron.* (page 213) on the R.H.S. fruit and vegetable show. I know I am only doing what hundreds would like to do in thanking you, especially for drawing attention to the miserable value of the prizes offered. The amateur element was sadly lacking, as you rightly observe, and the reason is given in Mr. Lewis Smith's letter (*Gard. Chron.*, p. 238). I thoroughly agree with Mr. Smith that the show was the worst seen for sixteen years. I have known the R.H.S. shows for over forty years, yet never have I seen such a poor display as at the one in question, and I have never heard so much complaining at previous exhibitions. The present season has been one of the worst for fruit growing, but even that would not have made such a difference to the show if the would-be exhibitors had been allowed to place their produce on the tables. Mr. Smith sent fifty-two entries. I sent fifty-seven; thus there were one hundred and nine entries from two potential exhibitors. I know other gardeners who were not permitted to enter, and I hope they will come forward and state their case, so that the general public, at least, may know where the fault is. I had not the slightest idea that the date of entry was advanced a fortnight. I made application for a schedule to the R.H.S. secretary at the end of May, writing thus: "Please forward fruit and vegetable schedule when ready." To this I received no reply. Another postcard was sent early in July, with the same result, and again early in August, but I did not receive a schedule in reply to my applications. I managed to secure one at last from the Wisley Gardens, which are not far from us. Then I found I was too late, according to the advanced date for entries; however, I posted my entries, and explained why I was late. The answer came back—"Too late." Correspondence ensued, and ended by the secretary stating that no application had ever been made for a schedule by me. I can only say I did make application by postcards; but, of course, I am unable to state whether these reached Vincent Square. I receive schedules from all parts of the country, without applying for them. Why not from the R.H.S.? Surely it would be wise to forward copies to all old exhibitors. Mr. Smith draws attention to the pilfering that was carried on at Holland Park Hall. I may add that the employees of one firm had over £14 stolen during the staging of their produce. I suggest the R.H.S. fruit and vegetable schedule be made more easily understandable in future, and, in conclusion, I protest against amateurs' exhibits being placed away in the galleries; several visitors to the recent show saw nothing of the up-stair exhibits, and were surprised to learn afterwards that they had not seen the whole show. *G. Carpenter, West Hall Gardens, Byfleet.*

Phygelius capensis.—The articles respecting this shrub by *A. T. J.* and *J. P.* induce me to add a few remarks respecting it. It is described in nurserymen's catalogues as herbaceous, and in the majority of cases it is planted in the herbaceous border. With the annual cleaning of the border, the plant is cut down with the rest of the subjects, to develop fresh shoots from the roots the following season, without ever a thought of trying it as a flowering shrub. No matter how grown, it is well worthy of a place in every collection, but to be seen at its best it requires to be trained against a wall. I have seen it grown in this way in Co. Down to a height of about 9 feet, and I understand it is to be seen in some of the southern counties grown as a wall shrub. Our winters of late have not been too severe, and I consider, in a number of places where this plant is grown as an herbaceous subject, if tried against a south or west wall, it would prove hardy enough to be grown as a shrub, and a very profuse flowering one. *J. T., Glasgow.*

SOCIETIES.

IMPERIAL FRUIT SHOW, MANCHESTER.

There is no doubt that the exhibition of hardy fruit which opened at the Belle Vue Gardens, Manchester, on the 26th ult., was the finest ever seen north of London, and a tremendous amount of credit is due to the various sections of the fruit industry for bringing about this satisfactory state of affairs. Except for the small exhibits section, the show was essentially commercial, and, though it was not to be expected that in a season when the Apple crop is below the normal the exhibits would be as numerous as they were last year at the Crystal Palace, the average quality was equally good, and the improvement in the packing of the home-grown fruit very marked.

But for the enterprise of the trade, the Imperial Fruit Show might have ended with the second exhibition, and Manchester, at least, has done its best to ensure its continuation, and all that seems to be wanted to make the Imperial Fruit Show an annual event is a continuation of the spirit shown on this occasion. The building at Belle Vue—a relic of war-time—lent itself well for the purpose of the show, the overhead light being good, and with the competitive exhibits arranged down the centre and the trade stands on either side the effect was highly pleasing. In addition to affording a display of splendidly grown fruit, the show was educational to a degree, there being demonstrations in grading, packing, cooking, and other things, as well as lectures and conferences, and the whole of the arrangements were carried out in a manner that reflected great credit on the Committee and the officials.

British Empire Section.

There was a very keen competition in this section, which is open to *bona-fide* commercial growers in any part of the British Empire, and in the class for ten boxes of any dessert Apple premier honours were won by the Associated Growers of British Columbia, Ltd., who showed McIntosh Red in perfect condition; Mr. F. P. Norbury, Malvern, came a close second with splendid Cox's Orange Pippin; third, Macdonald College, St. Anne de Bellevue, Canada, with McIntosh Red; fourth, Mr. F. P. Norbury, with Cox's Orange Pippin; and fifth, the Hollesley Bay Colony, with the same variety.

In the cooking section, Mrs. Norris Bomford, Salford Priors, Warwick, won with splendid specimens of Blenheim Pippin; Mr. F. P. Norbury coming a close second with Lane's Prince Albert in fine condition; and Mr. S. W. Mount, Patrixbourne, Canterbury, third, with Lord Derby. The Associated Growers of British Columbia took the fourth prize with Wagener; and Mr. F. P. Norbury won the fifth award.

In the Overseas section there were many fine exhibits of Apples which are familiar in the home markets, the awards for which took the form of medals.

Kent and Southern Counties Section.

There was little competition for six boxes of Cox's Orange Pippin, and the first prize was awarded to Mr. G. W. Layley, Beconham, Berkshire. Mr. Spencer W. Mount, Patrixbourne, Canterbury, had the best six boxes of Worcester Pearmain, his fruits being exceptionally fine; and Mr. H. G. Klienwort, Boughton Monchelsea, Maidstone, was second. In the Allington Pippin class, Mr. H. M. Cobb, Higham, Rochester, led, followed by Messrs. H. G. Klienwort and Mr. S. W. Mount. The boxes of Blenheim Pippin which won for Mr. Mount the first prize were of wonderful colour and quality. In the "any other variety" class, Mr. H. G. Klienwort won first place with King of the Pippins; Mr. S. W. Mount, second, with Gascoyne's Scarlet; and Sir Walter W. Berry, Faversham, third, with Charles Ross.

There was a poor competition in the class for nine half-sieves of Cox's Orange Pippin, and Mr. G. W. Layley was the only prize-winner, but his Apples were good. Worcester Pearmain of exceptional quality won in the class for half-sieves of "any other variety," and was shown by Mr. S. W. Mount; Mr. H. M. Cobb, Higham, Kent, was second with Allington Pippin; and Mr. H. G. Klienwort, third.

Bramley's Seedling Apples, in barrels, were very good, and here again Mr. S. W. Mount won, followed by Mr. H. M. Cobb, with fruits less well coloured; Mr. F. I. Neame, Chilham, third. In the Newton Wonder class (barrels), Mr. Mount was also the victor with splendid fruit, and Sir Walter W. Berry, second. For Lane's Prince Albert, in barrels, Mr. S. W. Mount won with splendid specimens; Mr. F. I. Neame being second; Mr. Selby Smith, Barming, third. In the class for barrels of "any other variety," Mr. Mount won with Lord Derby; Mr. H. M. Cobb, second, with Gascoyne's Scarlet; and Mr. S. W. Mount, third, with Bismarck. Mr. S. W. Mount had splendid sieves of Bramley's Seedling which won first prize; Mr. W. L. Hubble, Faversham, being a good second; and Mr. O. Ellis, Bramley, Surrey, third. With bushels of Newton's Wonder, Sir W. W. Berry won well, his Apples being very fine; Mr. H. M. Cobb was a good second; and Mr. S. W. Mount, third. For "any other variety" in sieve baskets. Mr. H. G. Klienwort led with Bismarck; Sir W. W. Berry, second.

Eastern and Northern Section.

The best six boxes of Cox's Orange Pippin Apples were shown by Mr. H. Granger, Maldon, Essex, the fruit being nicely finished and well packed. The Hollesley Bay Labour Colony came second, and Messrs. W. Seabrook and Sons, Chelmsford, third. In the Worcester Pearmain class, Col. B. J. Petre, Westwick Fruit Farm, Norwich, was deservedly placed first for highly coloured and well-packed fruit, followed by the Hollesley Bay Labour Colony, and Mr. W. P. Hartley, Holwell Bury Fruit Farm, Bedfordshire. The last-named exhibitor won first and second prizes in the class for Allington Pippin in boxes, Col. B. J. Petre coming third. Boxed Blenheim Pippins from the Eastern Counties were only of very moderate quality, and the Hollesley Bay Labour Colony won the premier award. In the class for "any other variety," Miss K. M. Courtauld, Earls Colne, won with Gascoigne's Scarlet, and the Hollesley Bay Labour Colony was placed second with Charles Ross.

Messrs. Gardner Bros., Wisbech, had the best nine half-sieves of Cox's Orange Pippin, the Hollesley Bay Labour Colony coming second, and Mr. H. Granger third. For half-sieves of "any other dessert Apple," Col. B. J. Petre won with choice fruits of Allington Pippin, followed by the Hollesley Bay Labour Colony with the same variety, and Mrs. J. C. Blofield, Wroxham, Norwich, with Worcester Pearmain, in this order.

Some fine Bramley's Seedling-Apples in barrels came from the Eastern Counties, and Mr. F. J. Cunningham, Wisbech, well won the first prize, Col. B. J. Petre being a close second and the Hollesley Bay Labour Colony third. Mr. J. E. Morton showed the best half-barrels of Newton Wonder, Col. B. J. Petre being second, and Mr. W. P. Hartley, Hitchin, third. In the half-barrel class for Lane's Prince Albert, Col. Petre was again at the front, followed by Messrs. B. Hull and Son, Ely.

Newton Wonder Apples, in bushels, were well shown by Mr. W. P. Hartley, Col. Petre, and the Hollesley Bay Labour Colony, who won prizes in the order given, while for Bramley's Seedling, in bushels, the Hollesley Bay Labour Colony was first, Mr. F. Clayton, King's Lynn, second, and Mr. F. J. Cunningham, Wisbech, third. Messrs. Gardner Bros., Wisbech, won in the class for bushels of "any other variety" with good specimens of Lord Derby, the Hollesley Bay Labour Colony being second with Blenheim Pippin, also good; and Col. B. J. Petre, third. For any other variety of Apple shown in barrels, Mrs. J. C. Blofield, Wroxham, Norwich, won with fine examples of Lord Derby; Mr. S. T. Sharp, Wisbech, being second, with Bismarck; and the Hollesley Bay Labour Colony, third, with Mère de Ménage.

West and Midlands Section.

Here, again, there was a shortage of Cox's Orange Pippin in boxes, and Mr. J. Morton, of the Aston Fruit Farm, Newent, Gloucestershire, received the premier award, followed by Mr. B. J. Harding, Kilcot, Newent. Worcester Pearmains were very good for the season, Mr. A. Coldicott, Evesham, having the best boxes, and Mr. J. Morton coming second. Mr. B. J. Harding was a good first prize winner with Allington Pippin, followed by Mr. F. Paget Norbury, Sherridge, Malvern. Mr. B. M. Bomford, Salford Priors, won first prize for Blenheim Pippin, in boxes, with splendid fruits; the second prize exhibit, staged by Messrs. B. Bomford and Co., Evesham, was almost as good. In the "any other variety" class, in boxes, Mr. B. J. Harding won with splendid samples of King of the Pippins; Messrs. B. Bomford and Co., second, with the same variety; and Mr. J. Morton, third, also with King of the Pippins.

In the class for six half-sieves of Cox's Orange Pippin, the fruit from the Western Counties was well up to the average of this variety in the show, and Mr. C. R. H. Weekes, Bradninch, won the first prize, followed by Mr. B. J. Harding and Mr. B. Morris Bomford, Salford Priors, Warwick, in the order mentioned.

The half-sieves of King of the Pippins shown by Mr. J. Morton in the class for "any other variety" was one of the best exhibits in the show, and the fruits of Worcester Pearmain shown by the Erdiston Farming Co., Stockton, Worcester, which came second, were also very good; Mr. B. J. Harding was third with nicely coloured King of the Pippins.

In the Bramley's Seedling, barrel, class, Mr. F. P Norbury was a good first; the Erdiston Farming Co., second; and H. J. Pewtress, third. Mr. F. P. Norbury had the best Newton Wonder Apples in barrels, followed by the Erdiston Farming Co. For Lane's Prince Albert, Mr. J. Morton was the chief prize-winner; and Mr. F. P. Norbury, second. For "any other variety," in half-barrels, Messrs. B. Bomford and Co. won with fine Blenheim Pippin; and Mr. F. P. Norbury came second with Lord Derby.

Splendid fruits of Bramley's Seedling, shown by Mr. B. J. Harding, won first prize for sieves of that variety, the Erdiston Farming Co. being second, and Mr. W. T. Allen, Glastonbury, third, with fruit showing less colour. Mr. A. Coldicott, Evesham, won well with Newton Wonder, in sieves; Mr. H. J. Pewtress coming second. In the class for "any other variety," in bushels, the first and second prizes were divided between Mr. B. M. Bomford and the Erdiston Farming Co., who showed Blenheim Pippin and Warner's King respectively; Mr. F. P. Norbury was placed third.

Channel Islands Section.

Fruit from the Channel Islands was not extensively represented. Mr. E. Bull, St. Heliers, Jersey, was the only exhibitor in the class for six boxes of dessert Pears, and was awarded the first prize. There were no Grapes, and in the class for seven baskets of Tomatos, indoor grown, Mr. C. J. Summer, St. Aubyns, Jersey, excelled; while in the class for outdoor Tomatos Mr. J. Michell, St. Saviours, led.

Ulster Section.

It must be placed to the credit of the Irish growers that they showed better Apples than they did last year at the Crystal Palace, and these were also packed much better, but the Ulster men have yet a long way to go before they will be able to compete successfully with English growers.

Pears.

As might have been expected this year, Pears were not strongly represented, and the chief prize-winners were Mr. E. Bull, Jersey; the Hollesley Bay Colony; Mr. B. M.

Digitized by Google

Bomford, Mr. H. M. Cobb, and Messrs. F. and T. Neame.

Special Prizes and Trophies.

There are so many special prizes, trophies, challenge cups, and medals offered at the Imperial Show that an exhibitor hardly knows what he stands to win, and this year the number has been added to. Amongst the numerous trophies are the gold cups presented by the *Daily Mail*. The one in the United Kingdom section was won by Mr. S. W. Mount, and in the Overseas section by the Associated Growers of British Columbia. Mr. S. W. Mount won the gold cup presented by Mr. C. H. Deakin, and a similar cup presented by Messrs. Dingleys, Ltd., went to Mr. H. M. Cobb, Higham, Kent. Many other silver cups, pieces of plate, trophies, and medals were awarded to different prize-winners in the various sections.

Small Exhibits Section.

The long length of tabling devoted to single dishes of Apples reminded one of the R.H.S. Fruit Shows, but we failed to see fruit in this division that was in any way superior to that shown in bigger lots in the commercial division, while some of the exhibitors won prizes in both sections.

In the class for a dessert Apple in season in November and December, Mr. C. R. H. Weekes, Bradninch, won with a fine dish of Cox's Orange Pippin, Mr. H. Hales, Sittingbourne, coming second with Allington Pippin, and Col. A. S. Fitzgerald, Lockerley, Romsey, Hampshire, third, with Blenheim Pippin. For a dish of dessert Apples in season after Christmas, the first prize went to a dish of Lord Hindlip, shown by Mr. H. J. Pewtress, Hereford, the second award being won by Mr. J. A. Stidston, Bishops Teignton, Devon, with a fine dish of Sir John Thornycroft; Mr. H. J. Phelps, Tibberton, Gloucester, third, with Court Pendu Plat, which were fine specimens of the variety.

In the dual purpose class there were Apples of different sizes and many varieties, and the first prize was given to some large specimens of Gascoyne's Scarlet, with a fine skin, but very poor colour; Mr. H. L. Thompson, Ottawa, Canada, was placed second with Wealthy, which were quite good; Mr. F. P. Norbury, Malvern, third, with Newton Wonder.

For a dish of an early, cooking variety, Mr. R. W. Thatcher, Market Harborough, won with Peasgood's Nonsuch; Mrs. J. Bond, Olantigh Gardens, Wye, second, with Lord Derby; and Col. C. R. Rowley, Felixstowe, third, with Peasgood's Nonsuch. Mr. W. T. Allen, Glastonbury, had the best dish of a late culinary variety, showing Bramley's Seedling; Mr. D. W. Ivison, second, with Alfriston; and the Coldstream Ranch, British Columbia, third, with Rome Beauty.

Pears only made a moderate show, and the Hon. Mrs. Pike, Westwick House, Norwich, won with very fine fruits of Doyenné du Comice, second, Mr. J. Michell, St. Saviours; third, Mrs. C. M. Solley Flood, Crickhowell.

Trade and Miscellaneous Exhibits.

It was a matter for regret that at a show of such commercial importance exhibits from many leading nursery firms and appliance manufacturers were conspicuous by their absence, but we saw evidence, nevertheless, of the commercial enterprise of Manchester and district. In the centre of the building, Messrs. Geo. Monro, Ltd., Covent Garden, had one of their characteristic displays of fruit most tastefully arranged; and Messrs. W. Seabrook and Sons, Chelmsford, also made a very fine display of fruit and fruit trees. Mr. John Swift, Manchester, who worked so hard in the interests of the show, had a fine stand of fruit; and Mr. C. H. Deakin's Watercress bed, showing how the salad is grown under hygienic conditions in spring water, was highly interesting.

Various organisations, including the Federation of British Growers, the National Farmers' Union, and the Wisbech and District Fruit Growers' Association, had exhibits; and there were educational stands from the Ministry of Agriculture, the Botanical Department of the University of Manchester, East Malling Research Station, and Long Ashton, while the various Overseas Dominions were represented by wonderful displays of fruit. Individually and collectively, the "miscellaneous" exhibits, which were of a varied character, added a feature of interest to the show, which appeared to be appreciated by the visitors.

ROYAL HORTICULTURAL.

October 30 and 31.—The display at Vincent Square on these dates was a magnificent one, and very largely composed of groups if Orchids. The exhibition was a special one in that Orchid growers were encouraged to exhibit, and they responded with great enthusiasm and great purpose. Not so very many years ago such a display of Orchids would have been impossible at this time of year. Other notable features were the Carnations, Chrysanthemums, hardy flowers, Scabious, stove plants, vegetables and fruits. The attendance was large.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), The Hon. H. D. McLaren, Messrs. Jas. O'Brien (Hon. Secretary), Gurney Wilson (Assistant Secretary), J. E. Shill, R. Brooman White, H. G. Alexander, Arthur Dye, Richard G. Thwaites, Fred. K. Sander, C. J. Lucas, Frederick J. Hanbury, S. W. Florv, H. T. Pitt, H. H. Smith, J. Cypher, W. H. White, W. H. Hatcher, T. Armstrong, A. McBean, E. R. Ashton, J. Wilson Potter, Pantia Ralli, Charles H. Curtis, and W. J. Kaye.

Awards of Merit.

Odontonia Philosopher (*M. St. Andre* × *Odm. Harwoodii*), from H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood). A very distinct hybrid of Odontoglossum shape, with light yellow ground, evenly spotted with claret red, and with claret-red lines at the base of the lip.

Sophro-Laelio-Cattleya Pervanch (*C. Syros* × *S.-L.-C. Marathon*), from H. T. Pitt, Esq. A grand flower of true Cattleya shape; the broad sepals and petals are rose-coloured, flaked with gold, and the front of the lip is deep crimson.

Cypripedium Phantasy var. Sobriety (*Gloriata* × *Actaeus Bianca*), from H. T. Pitt, Esq. A flower of fine form, the Holfordian C. Actaeus Bianca giving both fine shape and colour. The ground colour is yellow tinged with purple; the upper half of the dorsal sepal is pure white.

Brasso-Cattleya Floss Flora (*L.-C. Soulange* × *B.-C. Ilene*), from H. T. Pitt, Esq. A flower of perfect form, coloured rosy-mauve, with a crimson purple lip and broad, yellow disc.

Laelio-Cattleya Profusion (*L.-C. Serbia* × *C. Hardyana*), from Messrs. J. and A. McBean, Cooksbridge. One of the finest and most perfect of hybrids raised at Cooksbridge, good in shape, size and colour. The sepals and petals of the plant shown were bright rosy mauve, the broad lip ruby-crimson, with yellow disc.

Odontoglossum Desdemona var. Rubens (*Rossii* × *illustrissimum*), from Messrs. J. and A. McBean. A charming and very distinct Odontoglossum, with spotted sepals and petals, and broad, rose-pink-coloured lip.

Cattleya Pittportia, var. Lady Leon (*Mrs. Pitt* × *Portia*), from Sir Herbert Leon, Bletchley Park. A very pretty hybrid, nearest to C. Portia, with fine trusses of mauve flowers and a purple lip.

Groups.

Baron Bruno Schroder, the Dell Park, Englefield Green (gr. Mr. J. E. Shill), was awarded the large Challenge Cup for one of the finest groups ever staged, perfect in the fine culture and profuse blooming of the plants, most of which had been raised at The Dell. In the centre was a noble specimen of Laelio-Cattleya Tiresias (L.-C. elegans × C. Bowringiana), with twelve spikes bearing together over two hundred bright mauve-purple flowers. Other Bowringiana crosses were equally well displayed, with the Dell forms of Laelio-Cattleya Ivanhoe, L.-C. Schröderae and others of the large-flowered hybrids for which The Dell gardens are famed, and grand Brasso-Cattleyas and Brasso-Laelio-Cattleyas, especially of the yellow type. Mr. Shill was awarded a Silver-gilt Lindley Medal for the excellence of cultivation shown in this exhibit.

Sir Jeremiah Colman, Bt., Gatton Park (gr. Mr. Collier), staged a selection of cut spikes of Gatton hybrids in which blue tints have been evolved by long selection. Cattleya Portia, Gatton Park variety; C. Ariel var. coerulea and others well exemplified the nature of the work: Brasso-Laelio-Cattleya Antoinette, Gatton Park variety, a model flower, and Laelio-Cattleya Copper King were also of new colours. The pretty tassel-like Bulbophyllum lemniscatoides was also shown.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), who gained most of the awards made by the Orchid Committee to novelties, staged a very fine group rich in good Odontoglossums, Odontiodas and Cypripediums, with an interesting selection of species, amongst which were forms of Bulbophyllum and Cirrhopetalum, including the graceful, copper-red C. Mastersianum.

Pantia Ralli, Esq., Ashtead Park (Orchid grower, Mr. Farnes), staged an excellent group, in the centre of which were fine Vanda coerulea and graceful yellow Oncidium varicosum, the sides being filled with showy Cattleyas, Laelio-Cattleyas, and other hybrids (Gold Medal).

J. J. Joicey, Esq., The Hill, Witley, staged a good group of Cattleyas, Laelio-Cattleyas, and Odontoglossums. The central plant was a grand specimen of the large, pure white Miltonia vexillaria Lambeauiana, with a heavy spike of many large flowers. Of the Laelio-Cattleyas, L.-C. Linda splendens was one of the best. Some good white Cattleyas were also shown, and among species the elegant white Coelogyne Veitchii, the blue Dendrobium Victoria Regina, the singular Oncidium longipes, and graceful Cirrhopetalum gracillimum were noticed (Silver-gilt Flora Medal).

Messrs. Charlesworth and Co., Haywards Heath, were awarded a Gold Medal for a grand group occupying about 250 square feet, and in which the best selection of most of the popular Orchids of the day and their new hybrids were well displayed. The centre of the exhibit contained about twenty-five fine forms of the firm's home-raised Odontoglossum crispum of their "Doin" type, which far surpass imported forms, as their richly-coloured, blotched forms raised at Haywards Heath have the coloured type. A number of the large white Phalaenopsis amabilis Rimestadiana, and some fine white Cattleyas and Miltonias also effectively enhanced the display, and their yellow-petalled Laelio-Cattleyas and Brasso-Cattleyas included good new forms. A selection of new Odontoglossums and Miltonia hybrids with their first flowers was also shown.

Messrs. J. and A. McBean, Cooksbridge, in their select group, had as the main feature plants of their beautiful Laelio-Cattleya Profusion (C. Hardyana × L.-C. Serbia), which they consider to be one of the finest crosses they have made. The plants shown had their first flowers, and it was evident that they are free growers and profuse in flowering, the trusses of large richly-coloured blooms being evidence that it is a standard florists' flower. Several forms were shown, all good in every respect. Messrs. McBean also showed some good forms of their L.-C. Linda and other of the Cooksbridge hybrids, including Brasso-Cattleya Lisette; B.-C. Ilene delicata and superb forms of Cattleya Luegeae and Hardyana crosses (Gold Medal).

Messrs. Sanders, St. Albans, staged a very fine group, replete with good hybrid Cattleyas, Laelio-Cattleyas, and Odontoglossums, with a very interesting selection of rare species. Outstanding plants were the new Odontioda Aurora Borealis, a large Odontoglossum-like flower, with white ground, tinged with mauve and blotched with purple; Cattleya Fabia Dreadnought, of

Digitized by Google

fine size and shape and rich colour; Brasso-Cattleya Ilene October, a model mauve flower, with round, crimson-purple lip; some good yellow Brassavola hybrids, and a selection of rare species (Gold Medal).

Messrs. COWAN AND CO., Southgate, staged a fine group in which their hybrids of the season were well shown, and especially their fine, white-petalled varieties of Cattleya Hassalii and C. Hardyana. Good Brasso-Cattleyas, for which this firm is famous, and a selection of Cypripediums were also shown (Silver-gilt Flora Medal).

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, staged a good group of Cattleyas, Laelio-Cattleyas, and other hybrids, with some pretty species. Laelio-Cattleya Cumbe var. Rainbow, is a model flower of fine colour. A choice form of their Brasso-Laelio-Cattleya Truffautiana was also noted (Silver-gilt Flora Medal).

Messrs. J. CYPHER AND SONS, Cheltenham, had a fine group in which Cypripediums were shown better than in any other exhibit. The collection included a selection of rare species. The best of the Cypripediums were C. Elatior, Shrubbery variety, the finest of its class; C. Dreadnought, of the best old type; C. Felicity, a modest, but distinct, light form. Varieties of C. insigne crosses and other leading types were also shown, with specimens of the elegant Platyclinis Cobbiana, bearing numerous sprays of white flowers. A fine plant of the now rare Selenipedium macrochilum giganteum was also shown (Silver Flora Medal).

Messrs. MANSELL AND HATCHER, Rawdon, Leeds, had a very effective group of finely flowered Miltonias, Cattleyas and Odontoglossums. Great variety and good culture was shown in the group (Silver Banksian Medal).

Messrs. FLORY AND BLACK, Slough, staged a very effective group, with good Odontoglossums, Cattleyas, Laelio-Cattleyas and Brasso-Cattleyas, for which a Silver Flora Medal was awarded.

Mr. HARRY DIXON, Wandsworth Common, had a very effective group of Cattleyas, Laelio-Cattleyas and Cypripediums. The group was well staged, and the plants in fine condition (Silver Banksian Medal).

Floral Committee.

Present: Mr. H. B. May (in the chair), Sir W. Lawrence, Messrs. J. F. McLeod, A. Williams, J. W. Barr, W. J. Bean, G. Reuthe, John Heal, W. Howe, C. R. Fielder, G. Harrow, J. B. Riding, Donald Allan, Reginald Cory, Sydney Morris, R. C. Notcutt, W. P. Thomson, D. B. Crane, W. B. Gingell, W. G. Baker, Chas. E. Shea, Chas. E. Pearson, J. W. Blakey, Andrew Ireland, Hugh Dickson, T. Hay, James Hudson, and W. B. Cranfield.

AWARDS OF MERIT.

Buddleia auriculata.—A free-growing, long-branched shrub, with twigs that extend horizontally. The lanceolate leaves are green above and white beneath. The small pinkish-white, green-tubed flowers are borne in terminal and axillary clusters, and as these clusters are freely borne, the effect of a shrub in full bloom is graceful and effective. As a late flowering shrub this Buddleia is desirable provided it can withstand inclement weather in most districts. Shown by the DIRECTOR, Royal Gardens, Kew.

Berberis Comet.—A gorgeous Berberis, and if any complaint is to be laid against it, it must be that it fruits too freely, for on some of the growths the coral-coloured berries were so thickly clustered that they made the slender shoots appear stiff. Where the shoots are branched the effect is finer, as there is less rigidity and far more grace. Nevertheless, Comet is certainly one of the finest of the hybrid Barberries. Shown from the ROYAL HORTICULTURAL SOCIETY'S Gardens, Wisley.

Nerine White Knight.—In this large-flowered variety the white, waved segments have in most cases a thin, median band of green. The tips of the segments recurve slightly. Shown by Messrs. BARR AND SONS.

Chrysanthemum Golden Marvel.—A handsome, decorative variety of medium size, and with flattish florets of a rich orange-gold colouring.

Chrysanthemum Mrs. E. Reeves.—A very pleasing decorative variety, with slightly curled and narrow golden yellow florets. It is a very attractive Chrysanthemum, and the blooms are carried on stiff, dark stems. These two varieties were shown by Mr. G. CARPENTER, West Hall Gardens, Byfleet.

Chrysanthemum Raleigh.—This handsome single-flowered variety has blooms of a brilliant crimson colour with golden centre. The florets are flat and regular.

Chrysanthemum Exmouth Pink.—A medium-sized, single-flowered variety; its pleasing colouring is a lively shade of rose-pink. The two last-named varieties were shown by Messrs. GODFREY AND SON.

Chrysanthemum Mrs. T. Hancock.—A grand, large-flowered single variety, with two or three rows of flattish florets. The basal colour is primrose, but this is heavily overlaid with rich pink, and the effect is very fine. Shown by Messrs. GODFREY AND SON, and Messrs. K. LUXFORD AND CO.

Chrysanthemum Nona. Another fine single variety, with several rows of broad, slightly recurving, white florets. Shown by Messrs. KEITH LUXFORD AND CO.

GROUPS.

No doubt in anticipation of the annual show of the National Chrysanthemum Society later in the week Chrysanthemums were a prominent feature of the groups which came before the Floral Committee. Mr. H. J. JONES set up a very imposing collection, which included a great number of very good blooms. Against the wall he had tall stands of such exhibition Japanese varieties as Majestic, Mrs. R. C. Pulling, Mona Davis, and an excellent seedling. A large stand of mixed incurved sorts, chiefly Buttercup, was also very effective. As a groundwork, and in front Mr. JONES arranged decorative masses of Uxbridge Pink, Golden Glory and Pink Delight, of the market Japanese type, and such singles as Sandown Brilliance and Mrs. Edwards (Silver-gilt Flora Medal).

Messrs. KEITH, LUXFORD AND CO. used large quantities of spray-flowered varieties to good effect. These were mostly arranged in baskets, with a back row of tall stands. Their principal varieties were Almirante, Betty Sparkes, Lichfield Purple and Goldfinch (Silver Flora Medal). Undisbudded sprays were also shown by Mr. WM. YANDELL, who had gorgeous masses of Red Almirante, Crimson Pride, Shrapnel and Hesperus (Silver Banksian Medal).

Nina Blick, Almirante, Perle Chatillionaise, Verona, and similar decorative varieties of Chrysanthemum were shown by Messrs. CARTER, PAGE AND CO. (Silver Banksian Medal). Messrs. J. GODFREY AND SON had mostly singles, and these included Exmouth Pink, Laura Vickary, Distinction and Ruby, of perfect form and beautiful colouring (Silver Banksian Medal).

Just inside the entrance Messrs. L. R. RUSSELL had set up a group of magnificently grown stove plants. There was a great variety of Codiaeums (Crotons) and Cordylines (Dracaenas) bearing brilliant colours. Amongst other plants of merit there was an Aristolochia, Passiflora princeps, and, raised on stands, plants of Columnea gloriosa, particularly well flowered, also Nepenthes Sir W. T. Dyer, bearing "pitchers" over a foot long (Silver Flora Medal).

Col. H. C. ELWES, D.S.O. showed a small group of the excellent Nerines for which Colesborne is famed. The plants were all of great merit, and their beauty was enhanced by a decoration of berried sprays of Berberis Wilsonae (Silver Flora Medal).

Mrs. SOFER WILBURN (gr. Mr. A. S. Gooden), Amport St. Mary's, Andover, exhibited a group of splendidly grown winter-flowering Begonias. These were in relatively small pots and carried immense heads of beautiful flowers. The chief varieties were Elatior, Flambeau, Eclipse and Optima (Silver Flora Medal).

A small collection of Primula obconica Eureka, salmon pink, was shown by Messrs. HURST AND SON. The plants were very sturdy and bore large and shapely flowers, illustrating an exceedingly desirable strain.

Particularly good Carnations were staged by Messrs. ALLWOOD BROS., who set up many of their own varieties, with also a quantity of the graceful Dianthus Allwoodii. At the corner of the Carnation group there was a particularly attractive bowl of Mrs. C. F. Raphael (Silver Flora Medal). Mr. C. ENGELMANN included Topsy, Tarzan and Maine Sunshine in a good collection of Carnations (Silver Banksian Medal).

Roses were shown by the Rev. J. H. PEMBERTON, who had vases of Moonlight, Mermaid, Mary Monro, Mrs. Christie Miller, and Sammy (Silver Flora Medal). Messrs. WHEATCROFT BROS. included Emma Wright, The Queen Alexandra Rose, Lamie and Golden Emblem in their collection (Silver Banksian Medal). Mr. E. J. HICKS brought several vases of the new H. T. America, which is a very shapely pink variety, and has long, stout stems. Violets were shown by Mr. J. J. KETTLE (Bronze Banksian Medal), and by Mr. H. B. PINNEY, who included several pinkish-coloured varieties, which attracted attention (Bronze Flora Medal).

The new Chrysanthemum Golden Marvel was shown in moderate quantity and considerable beauty by Mr. F. C. WOOD, who also had good plants of Primula capitata and the double-flowered Daisy, Dresden China. He also showed miniature rock gardens (Bronze Banksian Medal).

Messrs. BAKERS, LTD., filled a long stretch of tabling with hardy border flowers, chiefly Michaelmas Daisies, Scabious and Kniphofias (Silver Banksian Medal). The Misses HOPKINS made an attractive little rockery, which they planted appropriately, and also showed hardy border flowers. Messrs. WALLACE AND CO. displayed several vases of the pink-flowered Schizostylis coccinea Mrs. Hegarty.

A large collection of their Scabious hybrids was arranged by Messrs. I. HOUSE AND SONS. These illustrated a long series combined with considerable beauty (Bronze Banksian Medal). Messrs. LOWE AND GIBSON exhibited a small collection of Gladiolus hybrids. The spikes were smaller than earlier in the season, but many of the colours were very attractive.

Fruit and Vegetable Committee.

Present:—Messrs. C. G. A. Nix (chairman), J. Cheal, H. S. Rivers, Geo. F. Tinley, S. B. Dicks, W. F. Giles, G. Reynolds, P. D. Tuckett, A. C. Smith, E. Neal, G. Woodward, W. H. Divers, E. A. Bunyard, H. N. Rawes, and A. W. Metcalfe.

Mr. J. T. GOOD, Bushy Grove Road, Bradfield, Hertfordshire, sent specimens of his new Apple Bushy Grove, which received an Award of Merit on January 31, 1922, for the higher award of a First Class Certificate. The variety is said to be available for use very early in the season and keeps until June. It is included in the trial of commercial varieties at Wisley, and it was left to see how the variety compares with others in the trial. Mr. GEORGE WOODWARD brought from Barham Court Gardens, Kent, splendid fruits of Doyenné du Comice Pear, observing that the fruits were less regular in contour than usual this season. They were, however, of remarkably fine quality, and in the opinion of many of the Committee some of the best Pears they had seen in this season of scarcity for Pears. Mr. WOODWARD stated that his finest cropping varieties this year were Durondeau, Conference, and Doyenné du Comice, all the trees of these varieties having borne profusely.

Messrs. BARR AND SONS, King Street, Covent Garden, W.C., were awarded a Silver-gilt Knightian medal for a remarkably fine collection of vegetables staged in a most attractive manner. The collection was a very comprehensive one, almost all kinds of vegetables being represented. At the back were some exceptionally fine heads of Autumn Giant, Autumn Mammoth, and Early London Cauliflowers, with splendid Leeks and fine heads of Celery. Plants of Brussels Sprouts were also very good. The Onions included large bulbs of Froxfield, Nuneham Park, and Ailsa Craig varieties, and other fine dishes were Silver Moss Curled Endive, New Intermediate Beets, Early Nantes and New Red Intermediate Carrots, Alderman Peas, Purple-eyed Potatos, and Cucumbers. In the centre of the exhibit was a collection of ornamental Gourds.

Digitized by Google

Mr. E. J. Parsons, Worcester, again showed a collection of Apples and Pears, for which a Silver Hogg Medal was awarded. Fruits of Gascoyne's Scarlet, Wm. Crump, Newton Wonder, Tyler's Kernel, Lord Hindlip, Bramley's Seedling, Chas. Ross, and Allington Pippin Apples were all of large size and fine quality generally. The Pears included large, luscious-looking fruits of Pitmaston Duchess.

Mrs. Reid, Devizes Castle, Devizes (gr. Mr. Thayer), showed a very good exhibit of Apples, Pears and Grapes. Amongst the Apples we noticed some very fine old sorts, including Tom Putt, Lemon Pippin, Bess Pool, Beauty of Kent, and Flanders' Pippin; whilst the Pears included exceptionally large fruits of Pitmaston Duchess and the old Bishop's Thumb. The Grapes were of the Black Alicante and Ryton Muscat varieties, both large of bunch and fine of berry (Bronze Hogg Medal).

Mr. W. Lane, Rickwoods, Cowden, Kent, showed eight dishes of Apples.

Messrs. Sutton and Sons showed types of Cabbages and Savoys; a very interesting and educative exhibit. They were of main crop and autumn varieties, and included Winningstadt, Imperial and Favourite Cabbages, the two last being splendid for both spring and autumn sowing; Rosette Colewort, a hardy winter green and Hardy Colewort, which is even hardier. The Savoys included Sugar Loaf, with very conical heads, Dwarf Green Curled, Perfection and Best of All. Of the Red Cabbages the finest sort was Large Blood Red.

Mr. Jasper Davis, Chippenham, showed large, shapely tubers of Potatos Victoria, Edward VII., Laing's Imperial, White City, Up-to-Date, and Ally.

Obituary.

Rev. H. J. Bidder.—We regret to announce that Henry Jardine Bidder, Fellow of St. John's College, Oxford, died on the 19th ult. after a brief illness following a long period of ill-health. By his death the University loses one of its most gracious and conspicuous ornaments and horticulture has to mourn the loss of a true and devoted friend. The Rev. H. J. Bidder, who was the son of a distinguished engineer, Mr. George Parker Bidder, was born at Mitcham, Surrey, in 1847. He was educated at Harrow and Oxford and became in 1873 a Fellow of St. John's, which position he held at the time of his death. Soon after the completion of his University undergraduate career Mr. H. J. Bidder took Orders, and thenceforth devoted his fine gifts and great energy to academic pursuits and the service of the Church. In the eighties the Rev. H. J. Bidder became Bursar of St. John's and rendered great service to the College by placing its finances on a firm basis. Always keenly interested in agriculture, forestry and gardening, he exerted himself strenuously and with great effect to interest his College and the University in these subjects. Thanks to him and other men of wisdom, the Sibthorpian Professorship of Rural Economy was re-endowed and a Professorship of Forestry was established. Always determined and often persuasive, he was able to secure the powerful support of his College on behalf of forestry, with the result that Bagley Wood was put at the disposal of the Forestry Department of the University as a training ground and Arboretum. But conspicuous as were his services to forestry and agriculture, those which he rendered to horticulture were no less remarkable. He cultivated the tradition of horticulture, kept it alive, fostered it when it might have languished, and made of St. John's garden one of the most beautiful places in the world. There he maintained the broad lawns and was wise to interfere but little with the shrubberies—knowing well that people have passionate predilections for those things and plants to which they have been accustomed. Gradually, here and there, almost imperceptibly he introduced among the shrubby relics which had grown old under the eyes of generations of Fellows and undergraduates choicer plants —climbers and flowering shrubs and herbs like the Meconopsis, so that by almost unperceived degrees the garden changed from commonplaceness to beauty. So gradual was the change that none resented and all enjoyed it. Then as his crowning triumph, discreetly —round the corner as it were—he faced an old wall with rockwork cunningly made with many pockets for alpines and underground water to keep them fresh, and so, in an impossible situation, he made one of the most famous rock gardens. Professional gardeners may and often do possess a far larger fund of knowledge than Mr. Bidder owned, but none knew better how to use it. It was as a guide in the St. John's garden that the Rev. H. J. Bidder was at his best. Proud of his plants and loving them, he would in later days, as his sight became dimmed, pore over them and with a pretended querulousness chide "gardener"—who like us all, loved him and the garden they had made between them—with some imaginary neglect. When we laughed at him in perfect friendliness he used to laugh too, for he had the genius for friendship. Gracious and charming and authoritative, with a large generous heart, he would never let a true gardener leave him without a present of rare plants. Nor might any go away without admiring again the true Dittany of Crete, the Broom from Mt. Etna, his fine specimens of Fabiana imbricata, which he liked, not only because of its beauty, but also because of its Heath-like habit and its alliance with the Potato family. As we left the garden laden with gifts and gracious memories he would accompany us to the gateway, and the last recollection of a memorable visit would be the tones of the kindly and beautiful voice advising us if we would cultivate alpine gardens to remember the three P.s of Horticulture—Propagate, propagate, propagate! Bidder was a great friend. Fools perhaps did not suffer him gladly, for he was armed against them with a firm impatience; but to those who loved him he was sweet as summer, a great personality, a great scholar and gentleman, and a great gardener. There was none of the numerous company that attended the memorial service at St. Giles' on Monday, the 22nd ult., whose eyes were not dim and whose hearts were not heavy, when with sad appositeness the choir sang :—

Thy Gardens and Thy gallant walks
Continually are green
There grow such sweet and pleasant flowers
As nowhere else are seen
There trees for ever more bear fruit
And evermore do spring.

May it be that the College which he served so well will evermore preserve the rock garden of St. John's as a memorial to the man who made and loved it.

TRADE NOTES.

The Technical Committee of the Chamber of Horticulture met on the 17th ult. The Secretary reported the receipt of a letter from the Controller of Horticulture stating that arrangements had been made for further investigation into the disease caused by Plasmodiophora brassicae, also a letter from the Ministry's mycologist with reference to diseased Tulip bulbs sent for investigation.

The Secretary then reported that, with a view to more efficiently replying to correspondents' technical questions and compiling technical reports, he had suggested to the chairman the advisability of appointing an honorary secretary having technical knowledge. Mr. T. Parker had been approached and had agreed to act in this capacity should the Committee wish. The Chairman expressed his agreement, and pointed out that such an appointment would further the Committee's work, and formally moved that Mr. Theodore Parker be appointed Hon. Secretary to the Technical Committee for the purposes of noting the Committee's deliberations, drafting replies to correspondents thereon, and compiling reports. The motion was carried unanimously.

The Secretary also reported that he had drawn up a scheme for closer co-operation with affiliated associations, and that the Federation of British Growers already had the scheme in working order, as could be seen by the number of questions now submitted by that Federation. Special forms for use by applicants for technical advice had been printed and circulated.

It was also proposed to strengthen the Committee by the addition of representatives of the above-mentioned Federation and the Horticultural Trades Association. Mr. W. P. Seabrook, having been nominated as the representative of the Federation of British Growers, was unanimously co-opted as a member of the Committee.

ANSWERS TO CORRESPONDENTS.

Celery Diseased : *R. F.* Your Celery plants are suffering from a bad attack of the infectious disease caused by the fungus Septoria petroselina Apii. As a preventive measure against attacks of Celery leaf blight, the seed should be treated with hydrogen peroxide, the twenty-volume solution being the best strength. Affected plants in the rows should be sprayed with Bordeaux mixture on the first appearance of disease.

Edible Australian Passion Fruit : *G. H. S.* We know no edible Passion fruit that is native of Australia. Your plant is most likely to be Passiflora edulis, a native of Brazil, which has been introduced to many sub-tropical countries. In England it requires to be grown in a warm greenhouse, or a house with an intermediate temperature of about 50° to 55°. It is a strong-growing plant, and requires plenty of room, and may not produce flowers until it is several years old. If grown in a large pot or tub in which growth is somewhat restricted, it should flower earlier. There are several other species of Passiflora which produce edible fruits, but they require tropical treatment.

Germination of Tomato Seeds : *Sceptic.* The average time for the germination of Tomato seeds sown in pots or boxes and placed in a temperature of about 70° is from six to eight days.

Names of Plants : *S. S. B.* Chrysanthemum Balsamita (Costmary).—*F. A. F.* Garden varieties of Pentstemons are so numerous and so much alike that we cannot undertake to name them.—Z. Calocephalus (syn. Leucophyta) Brownii.—*A. W.* 1, Yucca aloifolia variegata; 2, Y. aloifolia tricolor; 3 Ophiopogon japonicus argenteo-marginatus; 4, O. Jaburan variegatus; 5, Nephrolepis Whitmannii; 6, Coelogyne asperata; 7, a form of Laelia elegans; 8, Oncidium species (send in flower); 9, Dendrobium, send in flower; 10. Coelogyne cristata, with slightly variegated leaves; 11 and 12, send when in flower; 13, Begonia President Carnot; 14, Alyssum saxatile.

Pink-flowered Azalea Mollis : *P. P.* There are no pink-flowered varieties of the true Azalea mollis. For this colour the hardy Ghent Azaleas are the best; Roi des Belges, pink, and Bouquet de Flore, rose pink, are beautiful varieties. The nearest to this colour among the Azalea mollis forms are Compte de Papadopoli, rose, shaded orange, and Mrs. J. J. de Vink, creamy-rose.

Twin-flowered Cypripediums : *J. E. P.* The production of two flowers on a stem in the class of Cypripedium you indicate is the outcome of vigorous growth. If to have flowers so large as possible is the object, the second bud, usually the smaller, should be removed as soon as it appears; otherwise your plants seem to be well able to bear two-flowered scapes. The size of your Cypripedium Hestia mentioned is equal to the best that hybrid can attain.

The Biochemistry of Plants.

Everyone who is interested in the chemistry of plants will welcome the appearance of a second edition of The Hon. Mrs. Onslow's book.* Although this work is primarily intended for the botanist, horticulturists who possess some knowledge of the elements of modern chemistry will find large stores of valuable information in its pages. Among the subjects treated of most calculated to interest them are the plant enzymes, those specialist agents of the plant—and of the animal—which bring about rapidly and at ordinary temperatures in the living organism, chemical changes which can generally be performed outside the body only by the use of drastic reagents or high temperatures. Thus, as is well known, the starch which accumulates in leaves exposed to sunlight and passes away from them to be used or stored in other tissues is prepared for its passage through the plant by being converted by starch hydrolysing enzymes into sugar. And the sugar, moreover, arriving in some storage organ is reconverted into starch, probably by the action of the same enzymes. For the changes which enzymes set up are reversible. Hence they are expressively termed balanced reactions. With increasing knowledge of plant chemistry additions are continually being made to the number of the enzymes which may be extracted from plant tissues, and the essential and varied parts which they play in the life of plants becomes more and more clear. Thus there is evidence that enzyme action plays a part in the obscure series of changes brought about by chlorophyll and sunlight whereby from water and carbon dioxide organic substances, *e.g.*, sugar, make their appearance in the leaves. There is evidence also that enzymes play a great part in the down grade, respiratory changes, whereby sugar in the presence of oxygen, resolved into carbon dioxide and water, liberates energy for the conduct of the work of the plant. Though only the green cells of the leaves absorb effectively the sun's energy, all parts of the plant share in the benefits. The energy—derived from sunlight which disappears when the sugar of the leaf is manufactured—reappears when that sugar, caused to combine with oxygen, gives rise to those same compounds, carbon dioxide and water, whence in the green leaf it was derived. Another subject which will appeal specially to the horticulturist is the chemistry of the plant pigments concerned in the production of flower colour. Of the colours in flowers reds and blues are now known to be due to a class of complex chemical compounds known as anthocyans. Yellows, on the other hand, are often due to pigments contained in living granular structures, the plastids, and of different chemical composition from that of the anthocyans. Sometimes, as in brown Wallflowers and Gaillardias, bronze and crimson Chrysanthemums, and orange-red Nasturtium, the colour is due to a combination of the optical effects of both. Although knowledge of the chemistry of these pigments has grown and is growing rapidly, it has not yet reached the point when it can explain in detail how it is that different colour varieties of plants maintain each their several colours and transmit them often unfailingly to their descendants. Nevertheless, though the field which still awaits experimental exploration is vast, the record of achievement as shown in these pages is already so great as to encourage the belief that it will not be long before the chemist will illuminate by his discoveries all the obscure phases of the lives of plants.

* *Practical Plant Biochemistry* by Muriel Wheldale Onslow. Second edition, 1923. Cambridge University Press. Price 12s. 6d.

Rothamsted Experimental Station.—The following account of the history of the Rothamsted Experimental Station at Harpenden, Hertfordshire, is given in the Report of the Station for 1921-22. The Rothamsted Experimental Station was founded in 1843 by the late Sir J. B. Lawes, with whom was associated Sir J. H. Gilbert for a period of nearly 60 years. Lawes died in 1900 and Gilbert in 1901; they were succeeded by Sir A. D. Hall from 1902 to 1912, when the present Director, Dr. E. J. Russell, was appointed. For many years the work was maintained entirely at the expense of Sir J. B. Lawes, at first by direct payment, and from 1889 onwards out of an income of £2,400, arising from the endowment fund of £100,000 given by him to the Lawes Agricultural Trust. In 1904 the Society for extending the Rothamsted Experiments was instituted for the purpose of providing funds for expansion. In 1906 Mr. J. F. Mason built the Bacteriological Laboratory; in 1907 the Goldsmiths' Company generously provided a further endowment of £10,000, the income of which is to be devoted to the investigation of the soil, thus raising the total income of the Station to £2,800. In 1911 the Development Commissioners made their first grant to the Station. Since then Government grants have been made annually, and for the year 1922-23 the Ministry of Agriculture have made a grant of £22,030 for the work of the Station. Viscount Elveden, M.P., has generously borne the cost of a chemist for studying farmyard manure since 1913, and until his death the late Mr. W. B. Randall defrayed the salary of a biologist. The Sulphate of Ammonia Federation and the Fertiliser Manufacturers' Association jointly defray the cost of a Guide Demonstrator for the field plots. The laboratories have been entirely rebuilt. The main block was opened in 1919, and is devoted to the study of soil and plant nutrition problems; a new block is being erected for plant pathology. The library has been much expanded and now contains some 20,000 volumes dealing with agriculture and cognate subjects. The equipment of the farm has also been expanded. The most important development of recent years has been the reorganisation of the work of the Station so as to bring it into touch with modern conditions of agriculture on the one side and of science on the other. The general organisation of the laboratory is now completed; it is hoped to reorganise in the near future the farm and field work and to improve the field technique. The general method of investigation at Rothamsted is to start from the farm and work to the laboratory, or *vice versa*. There are four great divisions in the laboratory—biological, chemical, physical and statistical—which may be regarded as the pillars on which the whole structure rests. But the method of investigation differs from that of an ordinary scientific laboratory where the problem is usually narrowed down so closely that only one factor is concerned. On the farm such narrowing is impossible; many factors may operate and elimination results in conditions so artificial as to render the inquiry meaningless. In place, therefore, of the ordinary single factor method of the scientific laboratory, liberal use is made of statistical methods which allow the investigation of cases where several factors vary simultaneously. Thus in the crop investigations a large number of field observations are made; these are then treated statistically to ascertain the varying degrees to which they are related to other factors—such as rainfall, temperature, etc.—and to indicate the probable nature of the relationhips. Thus the complex problem becomes reduced to a number of simpler ones susceptible of laboratory investigation. It has been found desirable to widen the scope of the work by repeating some of the more important experiments elsewhere, and some twenty centres in different parts of the country have been selected for this purpose. In October, 1921, the Station undertook, so long as its funds should allow, to carry on the continuous Wheat and Barley experiments at the Woburn Experimental Farm, till then conducted by the Royal Agricultural Society, and Dr. Voelcker gives his services as Honorary Local Director. In December, 1922, E. D. Simon, Esq., generously placed his Leadon Court farm at the disposal of the Station for experimental purposes. This is being used as a large scale test of the soiling system for keeping dairy cows.

Royal Gardens, Kew.—Dr. A. W. Hill, F.R.S., Director of the Royal Botanic Gardens, Kew, will lecture on "The Work of the Royal Botanic Gardens, Kew," before the Royal Society of Arts, Adelphi, W.C., on Wednesday, December 5. Mr. Chas. A. Seward, Professor of Botany at the University of Cambridge, will preside at 8 p.m.

Challenge Cup for Orchids.—Owing to a printer's error, the award of the small Silver Challenge Cup to H. T. Pitt, Esq., Stamford Hill (gr. Mr. Thurgood) was omitted from our report of the R.H.S. meeting on November 3, p. 268. The fine and varied group shown by Mr. Pitt was a record amateur exhibit, and four out of the seven Awards of Merit recommended by the Orchid Committee for novelties were gained by this exhibitor, as well as the Challenge Cup. The group included a specially fine selection of Odontoglossums, some new Cypripediums, and an interesting selection of species.

Cocoa Cultivation.—One of the series of Cantor lectures to be delivered before the Royal Society of Arts this season is to be given by Mr. Samuel Davies, on November 12, at 8 p.m.; it is entitled "The Cultivation of Cocoa in British Tropical Colonies."

King of Sweden's Visit to the Linnean Society.—His Majesty the King of Sweden found time in the forenoon of the wedding-day of his son, the Crown Prince of Sweden, to honour the Linnean Society with a visit to inspect the relics of the great Swedish naturalist, Linnaeus, otherwise known as Carl von Linné, which are there preserved. Accompanied by Baron Palmstierna, Swedish Minister, and attended by his suite, the King arrived a few minutes after 10 a.m., and was received by Dr. A. B. Rendle, the President, the Officers, members of Council and staff. His Majesty examined the herbarium of Linnaeus, containing so many plant-types, the insects, fish-skins preserved as if they were plants, shells, the artificial pearls produced by Linnaeus, the copiously annotated volumes, rare books, and similar treasures. His Majesty graciously accepted a copy of the recently issued volume *Linnaeus*, by Dr. Daydon Jackson, with other books illustrative of the Master's labours. Before leaving the King signed the Roll and Charter-Book, on a specially illuminated page.

Cedar Chests.—Chests made of the heartwood of Red Cedar, Juniperus virginiana, are recommended by an American entomologist, Mr. E. A. Back* for keeping clothes from injury by moths. The characteristic odour of Red Cedar is due to a volatile oil present in the wood to an amount ranging from one to two per cent., and there is more of the oil in the heartwood, sometimes as much as two to four per cent. The aroma from the oil kills any newly hatched or young clothes moth larvæ that may be confined in the boxes with the clothing, and if the chests are made to fit tightly, so that none of the female moths can enter, such chests render clothes almost immune from attack. The oil cannot be depended upon to kill the moths or their eggs, or the worms after they are one-half to full grown, or after they are three or four months old. Neither will the chests kill all the pupae or chrysalids, but if the clothes are thoroughly cleaned, brushed or beaten just before they are placed in the chests, they should be tolerably safe from attack. Tight chests or cabinets made of other wood, the walls of which may be made to absorb as much Cedar oil as is found in the wood of containers of equal size made from Cedar wood, are said to be as valuable as the Cedar chests themselves. Amongst the preparations recommended by Mr. Back for treating clothing to protect fabrics, etc., from moths are naphthalene, paradichlorobenzene, carbon disulphid, and carbon tetrachlorid. The simplest of all methods is enclosing articles of clothing, furs, etc., in unbroken paper to form moth-proof paper bags. Clothes moths do not eat through paper to reach clothing, and if no other kind of paper is available, several thicknesses of newspaper will serve.

Swedish Prize Awarded to a British Scientist.—A prize fellowship of one thousand Swedish kronor, offered for research in science by the Swedish Federation of University Women, has been awarded to the Hon. Mrs. Muriel Wheldale Onslow, whose work on the biochemistry of plants is referred to on p. 271. Mrs. Onslow has already been an "N" Fellow of Newnham College, Cambridge, and in 1915 was awarded a fellowship of the British Federation of University Women. We congratulate Mrs. Onslow in gaining such a notable award, for the fellowship was open to the university women of eighteen countries.

The French Luxury Tax on Flowers.—The florists of Paris, combined in two syndicates—one national, the other comprising Parisian traders only—have won what they consider a notable victory, in that they have succeeded in getting the regulations relating to the luxury tax on flowers altered, so that the upward limit of value for funeral wreaths is placed at 150 francs. It will be remembered that for many years the luxury tax has been operative in France, and has weighed heavily on florists, flowers being considered in most instances a luxury and taxed accordingly. For a year past the Paris florists have fought to get the tax on funeral wreaths reduced, and their victory, though only a partial one, has been hailed with delight. Flower wreaths are now exactly on a level with artificial wreaths made of celluloid, "pearls," wax, etc., which, not used much in this country, are exceedingly popular on the Continent. A condition, however, is imposed in the case of wreaths of natural flowers, namely, that in every invoice the vendor must name the address of the buyer and of its destination, and the date and place of the funeral, in order that there can be no doubt as to the destination of the flowers in question. A writer in our contemporary, *L'Horticulture Française*, dealing with this point, waxes sarcastic over this restriction, and asks if the Government is afraid that a wreath ostensibly intended for a funeral is very likely to be sent, for instance, by a young man to his favourite dancer?

* Clothes Moths and Their Control, U.S.A. Department of Agriculture, *Farmer's Bulletin*, No. 1353.

Mr. John Coutts.—A native of Aberdeenshire and born on the Hill of Coull, Mr. John Coutts first learnt the art of gardening from his father, a keen amateur who was for many years a successful exhibitor of vegetables and florists' flowers. He served an apprenticeship at Haddo House, the Aberdeenshire seat of the Earl of Aberdeen, under Mr. J. Forrest, who taught his pupils the principles of gardening in a very thorough manner. From Haddo House Mr. Coutts went to Brentham Park, Stirling, under Mr. David Bruce, a fine old gardener. Here he served for two years as journeyman before going to Newstead Abbey, Nottingham, under Mr. A. McCulloch, where he had the advantage of assisting in several schemes of garden development and also obtained a knowledge of a very large collection of plants. His first position as general foreman was at Grantully Castle, Perthshire, where his experience was further increased as a consequence of considerable alterations and additions to the garden. From Grantully Castle Mr. Coutts went to Kew, where he was employed for four years in the flower garden, conservatory, tropical fernery and stove. For one year he was deputy foreman in the Palm House and for another year acted as deputy foreman in the decorative propagating department. From Kew he obtained an appointment as head gardener at Killerton Park, Exeter, the beautiful Devonshire seat of Sir T. D. Acland, Bt., and a garden famous for its collection of choice trees and shrubs and its extensive collection of Apples and Pears—the first tree of Doyenné du Comice Pear brought to this country is in the kitchen garden at Killerton. Sir Thomas and Lady Acland took a keen interest in their garden and during Mr. Coutts' stay of eight and a half years with them he made a new Rose garden, formed a rock garden and remodelled the pleasure grounds. In 1909 he was invited to return to Kew to take charge of the Decorative Department. He accepted the appointment, which he still retains, although his position has been improved and he is now one of the Assistant Curators at the Royal Gardens. Few men have such a wide knowledge of plants as Mr. Coutts, and few are better cultivators than he, consequently as chairman of the Kew Mutual Improvement Society since 1911 his knowledge has been of the greatest possible assistance to the young men at Kew. All old Kewites will know that Mr. Coutts has been treasurer of the Kew Guild since 1910, and they, better than all other horticulturists, know and appreciate his kindliness of heart and his readiness to render help in every possible way to those who are ambitious.

MR. J. COUTTS.

Gothenburg Exhibition.—According to our contemporary, *Die Gartenwelt*, the horticultural exhibits at the Gothenburg Exhibition were almost exclusively by Swedish, Norwegian, and Danish growers; and visitors to the exhibition are of opinion that the Danes have shown superior skill to either of their Scandinavian neighbours, the Swedish exhibits in especial showing little merit of form or colour. Among German firms, Teschendorff and Hermann Neuhoff were represented chiefly by Roses, while from this country, Mr. C. Engelmann, of Saffron Walden, had a display of excellent Carnations.

Cedars of Lebanon.—Our French contemporary, *Jardinage*, reminds us of the interesting fact that the Lebanon district now comprises only three Cedar plantations, of which one, situated on the eastern slopes of the Djebel Barouk, is composed not of the true species, but of Juniperus phoenicea. The second plantation, near the Hadebh, contains about six thousand young trees, and the third, which clothes the sides of the Makmel, contains the last vestiges of the Biblical Cedar forests, in which the four oldest trees measure between seventy and eighty feet in circumference.

Large Estates in Mexico.—Some of the estates in Mexico are, according to a correspondent in the *Times*, of immense extent, and he gives an example of one known as the Terrazas estate in the northern state of Chihuahua, estimated at over seven million acres, belonging to General Terrazas; "a horseman could ride across this kingdom for months without seeing a village, a mine, forest, pasture, orchard or vineyard, maguey or corn field, herd or flock, river or hill, that did not belong to General Terrazas." The Mexican Government decided that ten thousand square miles was more than one family could utilise, and proceeded to break up the Terrazas property. The owner was prohibited from completing negotiations for sale to an American company, six million acres were sequestrated and an army of engineers and surveyors employed by a semi-official organisation which has taken the land over at a price of about 5s. an acre. Another estate, known as the Durango property, covered more than a million acres, and there are two others of 600,000 and 400,000 acres respectively in the same State, whilst in San Luis Potosi, an American sugar-growing company's property extends to over one million acres, which is even eclipsed by the three million acres owned by an American cattle company in Lower California. The correspondent states that estates of two or three million acres are, or were, common. The distribution of estates is still proceeding, and in July it was announced that half a million hectares had been divided in one week. On August 2 last, a decree was issued by the Mexican Government enunciating the principle that every Mexican over eighteen years of age has a right to national lands; a minimum of three hundred acres may be owned by the simple act of occupation and giving notice to the Government, care being taken not to trespass upon private property, common lands of villages, or land already occupied.

Tuberisation said to be due to the association of the plant with fungi.—In a paper read by Dr. George H. F. Nuttall, of the British Association, reference was made to the origin of tubers in various plants. Prof. Nuttall referred to the occurrence of endotrophic mycorrhiza in the roots of species of Solanum and stated that Molliard, in experimenting with the Potato, found that tubers were not formed in aseptic cultures. Another investigator, Magrou, planted Potatos in a poor soil and found that only when the fungus present on Solanum Dulcamara infested the Potato plants, were tubers formed. Magrou investigated tuberisation in Orobus tuberosus and in Mercurialis perennis, and stated that when the Potato plant and Orobus were raised from seed the establishment of symbiosis leads to tuberisation of the sprouts at the base of the stem, and the tubers are not formed in the absence of symbionts. He further found that in developmental differences between the two plants, symbiosis in the Potato plant is intermittent, whilst in Orobus it is continuous.

Appointments for the Ensuing Week.—Monday, November 12: National Chrysanthemum Society's Floral Committee meets; United Horticultural Benefit and Provident Society's meeting. Tuesday, November 13: Royal Horticultural Society's Committees meet; St. Neot's Chrysanthemum Society's show. Wednesday, November 14: Lewes and District Horticultural Society's show (two days); Aberystwyth Chrysanthemum Society's show; Wimbledon and District Gardeners' Society's show; East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting. Thursday, November 15: Aylesbury Chrysanthemum Society's show; Grange-over-Sands and District Chrysanthemum Society's show. Friday, November 16: Blackburn and District Horticultural Society's show (two days); Dunfermline Horticultural Society's Chrysanthemum show (two days); Bolton Horticultural Society's show (two days); Leeds Paxton Society's Chrysanthemum show (two days). Saturday, November 17: Stocksfield Chrys. Society's show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Cultivation of Potatos.*—About the beginning of November I commenced planting, trenching the ground to the depth of eighteen inches as the operation proceeds. When the first trench is filled within six inches of the surface, I plant a line of Potatos, and sprinkle on the tubers equal portions of quicklime and soot (this is done to prevent slugs and other insects eating the Potatos), covering them with a layer of unfermented horse-dung, and then the soil; taking care not to tread on the fresh-planted ground. In the following March, as soon as the surface becomes dry, I have it either forked or hoed, and this operation is repeated as often as required. With respect to saving seed, my practice is to dig a sufficient quantity as soon as the skins are set firm, preferring the middle size for planting whole. Previously to the disease in 1845, I used to leave those intended for seed in the open-air to green, but by so doing in that year I lost half my seed; since that time I have them carried into the fruit-room or some other convenient situation, being careful to exclude the atmosphere as much as possible. The varieties I cultivate are Ash-leaved Kidneys, Early Frame, Early Manly and Fox's Seedling; but I believe any other sort would answer equally well, provided they were as early and dwarf in habit. The counties I have grown Potatos in are Staffordshire, Hertfordshire and Surrey; and whenever I have planted according to the above practice, the crop has always equalled my expectations, being ripe early and free from disease. *John Toy, Oatlands Garden. November* 1. *Gard. Chron., November* 4, 1848.

INDOOR PLANTS.

BIGNONIA GRANDIFLORA.

ALTHOUGH introduced so far back as 1800, Bignonia grandiflora is not common in cultivation, yet its ornamental character and exuberant growth make it a most valuable plant for covering walls or arbours. The fact that it has no fewer than five synonyms, given to it by various botanists, proves that it was at one time much sought after.

In growth it is very similar to B. radicans, but the flowers, which are borne on terminal, dichotomous panicles, are much larger and brighter. Young plants are less effective than older ones, as they are not so floriferous, but a wall furnished with a plant ten or twelve years old is a remarkable sight when in flower in July and August.

FIG. 98.—CHRYSANTHEMUM JEAN PATTISON. N.C.S. FIRST CLASS CERTIFICATE, NOV. 1 (SEE P. 283).

The plant is not exacting as regards soil, but a warm, sunny position is essential. Hard pruning should not be practised, as its effect is to produce very strong growths, which remain flowerless. When plants have filled their allotted space the only pruning necessary is to remove all dead wood and faded inflorescences. *W. Auton.*

LOSS OF SCENT IN THE MUSK.

THOUGH in recent years attention has been drawn from time to time to the loss of scent in the Musk (Mimulus moschatus) I am not aware that the matter has been thoroughly sifted. The view I have seen put forward that the loss of this fine perfume has been due to the introduction of a large-flowered scentless variety will not bear scrutiny. I know of several old-world gardens in this neighbourhood in which there has been no recent introduction of Musk—in fact, the plant in these is semi-wild, springing up here and there of its own accord—and yet in every case tested no perfume could be detected.

I well recollect as a boy the fragrant Musk, and how in passing the plant one almost involuntarily tore off a bit, and held it up to one's nose to enjoy its odour. If it had not been for its fragrance, which appears now to have vanished, it would never have become the favourite it was as an inmate of the garden and as a pot plant for the window.

When, it may be asked, was it first observed to have lost its scent? Does anyone now in this or other country possess the old-fashioned fragrant Musk? Nurserymen's catalogues, I see, still call attention to its fragrance! Has the plant in its wild state also lost its odour?

If this Musk, wherever it occurs, is now scentless, it seems to me that, from the point of view of evolution, the fact is one of great significance. It looks as if a character can suddenly drop out of a species beyond recall—in this case a regrettable mishap, for the Musk without scent is a weedy thing. I trust the Mignonette will not play us such a trick! It is easy to imagine a scentless race of Musk arising from a chance seedling; but the sudden and total disappearance of this perfume throughout the species, if a fact, is so novel as to demand full investigation. *J. P. Carlisle.*

[We hope that this note may result in some reader, at home or abroad, restoring this delightful old plant, with its fragrance, to our gardens.—*Eds.*]

The Week's Work.

THE FLOWER GARDEN.

By G. TURNER, Gardener to EMILY, LADY AMPTHILL, Ampthill Park, Ampthill, Bedfordshire.

Ranunculus.—A bed or border of Ranunculuses is very showy in the spring, and the flowers are useful as cut blooms for indoor decoration. The Turkish or Turban section of Ranunculus is admittedly the hardiest, and may be planted from now onwards through the winter in open weather. Other types may be planted in February. While any ordinary soil will suit this plant, the enhanced floral results will more than justify the improvement of ground that is poor.

A Late Shrub.—Always late in flowering, Clerodendron trichotomum will, this season, fail to open with us, for now, the last week of October, only one or two signs of the reddish bracts are visible—so there can be no chance for the fragrant white blossoms that should follow. In spite of this failure, however, it is a shrub that should be planted in a sheltered, warm spot, for in such a situation it will flower in most seasons. Its saving grace is in its lateness of blooming, when other shrubs are over.

Planting.—On all but quite light ground planting has been impossible, owing to the heavy rains of October, which have made the soil too sticky to work pleasantly. When the soil is drier the work of planting should be proceeded with; practically all shrubs and trees require to be made firm in the ground at planting time, and this is impossible when the soil sticks to the feet of the operator. It may not everywhere be practicable, but it is a good plan to have to hand a load of fine, dry soil at planting time in order that a quantity may be worked in about the roots of choice or special subjects.

Spanish Irises.—These lovely flowering bulbs have flowers of varied and rich colouring. They will succeed in almost any kind of soil, and a few arranged in groups or massed in a bed make a gorgeous show in early summer. Planting may be done until the third week in December. This Iris does not object to partial shade. For supplying cut blooms the Spanish Iris is a most valuable plant.

English Irises.—These, too, may still be planted but should be afforded rather better soil than the former. The range of colouring is not so great as in the Spanish section, but the flowers of the English Iris are larger and they are later by two or three weeks—a valuable asset where Irises are planted for their garden value.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Early Figs in Pots.—Two excellent Figs for early forcing are St. John's or Pingo de Mel, and Violette Sepor, as these are not so liable to cast their fruits as others. Given a suitable structure and proper treatment, they seldom fail to produce a good crop of fruit. Now that the foliage has fallen, the trees should be closely examined for insect pests, the most troublesome being scale and mealy bug. White scale adheres tightly to the bark, and requires a moderately stiff brush to remove it effectually, using as an insecticide either paraffin emulsion or Gishurst compound. The immature tips of the branches are rather tender, and require careful treatment; it is always advisable to look over the trees a second time for any stray scales that may have been overlooked during the first operation. Mealy bug may be treated in a similar manner; this pest hides in the cracks and crevices, and it is therefore essential to thoroughly work the insecticide into such places.

Potting Figs.—This is best done before growth is completed, but it may still be done if carefully carried out. The compost should consist of turfy loam, thoroughly broken up, a liberal amount of old lime rubble or broken plaster, and a 6-inch potful of bone meal to each barrowload of soil. During the active season of growth the roots require copious supplies of water; it is therefore essential to use a potting compost which will not become sour through frequent applications of water. It is advisable when shifting trees into larger pots to allow a liberal amount of room to permit of a good top dressing when the trees are swelling their fruits. The fermenting material for plunging purposes needs to be of a mild and lasting nature, and should consist principally of leaves. If the bottom heat is principally derived from hot-water pipes, it is still advisable to use leaves for packing round the pots, and the warmth arising from them will be sufficient to start the trees steadily into growth. Very little, if any, heat will be needed from the hot-water pipes to maintain a temperature of 55° by day, and 60° at night during severe weather. Syringe the trees with tepid water on bright days and damp the floors and walls to create a humid atmosphere. Little watering will be required if the pots are plunged in moist, fermenting material.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Broccoli.—Broccoli plants have made very strong growth this autumn owing to the excessive rainfall and the mild weather; over four inches of rain fell in these gardens during October. If sharp frosts should occur before Christmas, the plants will be liable to injury owing to the growth being soft. It will therefore be wise to lay the plants in with their heads to the north. Take out a spit of soil close to the stems on the north side of the rows, bend the plants over, and place the soil on the stem behind them. Have plenty of protecting material at hand to spread over the stems in the event of very cold weather occurring.

French Beans.—If a supply of these Beans is required during the winter, sow five seeds in each eight-inch pot. The receptacles should be well drained, and about half filled with a good, friable compost. Water the soil after the seeds are set, and germinate the latter in a temperature of 65°. Damp well between the pots, but guard against an excess of water at the roots. The seeds will soon germinate, and, as soon as the seedlings have made a pair of rough leaves, topdress them with rich soil, and place a few Birch broom twigs in the pots to support the plants. Keep the latter well syringed, and do not place them very near the hot water pipes, otherwise red spider will appear.

Carrots.—Carrots raised from seed sown in frames in the early autumn to provide small roots will now be ready for lifting and storing in sand. The frames may be lifted from the beds, and the old material wheeled on the garden to make room for forming fresh beds for early forcing. Frames in continual use on hotbeds should be overhauled, and any that need repairing attended to before they are required again. Two or three good coats of paint will help to preserve the woodwork, and the painting should be done, and broken glass made good, before the weather is very bad.

Trenching and Digging.—Advantage should be taken of fine weather to undertake these two operations as other work will be pressing in the New Year. It may not be possible to trench as much ground as one would like, but a certain amount should be trenched every winter. In trenching, much garden refuse may be buried with advantage to the ground, which is not possible in ordinary digging, and the resultant crops will be greatly benefited. In a dry summer, such as in 1921, the advantage of deep trenching was apparent to anyone who took notice, as, not only did the crops require less water, but they lasted longer and finished in better condition. The reason is the plants had a large area from which to draw moisture, for the roots were able to grow deeply and near to the damp sub-soil.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Shrubs for Forcing.—Numbers of hardy shrubs may be forced during the winter and spring. In cases where they are purchased they should be potted as soon as they are received from the nurseryman. If grown on the establishment the plants should be lifted and placed in suitable sized pots or tubs. After potting them they should be stood in the open until such time as they are required for forcing, protecting the pots from injury by frost by plunging them in ashes, or packing them round with hay. While some plants, such as Rhododendrons, Azaleas, Forsythias and Spiraeas may be lifted direct from the ground and potted at this time with good results, others, such as Lilacs, Pyrus, Prunus, Wistaria and Laburnum, give the best results when they are grown in pots, for they force more readily, and remain in flower for a much longer period when they are not disturbed at the roots. Hardy Azaleas, in their many beautiful varieties, are very popular, and may be had in flower over a long period. The early flowering Ghent or mollis varieties should be selected for early forcing. In forcing hardy plants it is important to select species and varieties that flower early naturally.

Other Good Shrubs for Forcing.—Spiraea arguta, S. prunifolia var. fl. pl., and S. Van Houttei are all excellent for forcing. Forsythia suspensa is popular and useful for forcing, but the best of all is the newer F. intermedia var. spectabilis, which is the earliest, and produces its deep golden yellow flowers in wonderful profusion. It may be had in flower about Christmas; it will remain in good condition in a conservatory for several weeks, and is ideal for furnishing a supply of cut flowers. Viburnum Opulus var. sterlis, and V. macrocephalum, have long been popular for forcing, but the fragrant V. Carlesii is not so well known. The last is a charming plant for growing in pots, and is best when allowed to develop slowly in a fairly cool house. Well budded plants of Magnolias are very beautiful for conservatory decoration, but they require careful handling, as they are impatient of disturbance at the roots.

Camellias.—These shrubs frequently set far more flower buds than the plants are capable of expanding; where this is so they should now be disbudded, as neglect in this respect generally results in wholesale dropping of the flower buds. Another common cause of bud dropping is dry conditions at the roots; although water should be given sparingly at this season, care should be taken that the plants do not suffer from lack of sufficient moisture at the roots. Camellias frequently suffer from attacks of scale insects, which should be removed by sponging with an approved insecticide, but a vigorous use of the syringe during the summer months will do much towards keeping the plants clean.

Pyrus and Prunus.—The best members of the Pyrus family for this purpose are P. floribunda and its varieties atro-sanguinea and purpurea; Pyrus spectabilis and P. Scheidekeri; while the Prunus include the many beautiful varieties of Japanese Cherries, P. Pissardii, P. japonica fl. pl. in pink and white varieties, and P. triloba var. fl. pl., while some of the beautiful double varieties of P. persica are very popular.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Pruning.—Where there is a considerable amount of pruning to be done the work should be commenced with a view to getting as much accomplished as possible before frost and snow render it impossible. Pressure of other work is always great in spring, and if all the trees, save the newly-planted ones, are pruned between now and then, it will be a great advantage. The theory that it is beneficial to prune transplanted fruit trees the same season as they are planted is gaining favour, and the belief is strengthened by the improvement of shrubs thus treated. A corresponding reduction of shoots appears to balance the check to the

Digitized by Google

roots. There is no necessity to wait until the leaves fall before pruning is attempted. The presence of the foliage may, in some cases, be of help in determining the amount of room required by the shoots it is desired to retain. It is advisable to defer pruning if frost threatens, or the bark of the newly-cut growth may split.

Planting.—The continued heavy rains have soaked the soil and reached the roots of most trees, and those who have been unable to lift their trees earlier through lack of a water supply will find them in good condition for removal. Trees that are suffering, but not very badly, from canker, should be lifted without a ball of soil, and replanted on a raised position. The following season may show even a more pronounced condition of the disease, due to the check caused by transplanting, but if the tree thrives the disease may gradually lessen each year, and the tree ultimately produce clean fruit, with the stems showing no tendency to canker. It is important that cankerous growth should be removed at an early stage. At this time of year the spores are liable to be washed down the tree stems or branches and enter any cut or bruised part of the bark. Badly-affected parts should be cut away and gas tar applied to the cut surfaces immediately. This is very important. In the case of Dumelow's Seedling (syn. Wellington) on a heavy soil every cut stem of this variety, however small, should be treated with tar, if spores of the fungus that causes canker are likely to be blown near the trees. Worcester Pearmain is also very subject to this disease

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Dendrobium formosum.—This Orchid flowers during the late summer and autumn, and requires a long season of rest. This species does not require large supplies of water, even during the growing season, and in winter very little moisture will suffice for its needs.

Calanthes.—The foliage of most of the earlier flowering Calanthes is fully ripened, and the plants will require very little water at the roots. If they are grown in a position where the soil becomes dry quickly, it is not advisable to deprive them of water entirely, even when the foliage has ripened. Whilst the roots of these plants are alive, they undoubtedly continue to give some sustenance to the newly-made pseudo-bulb for some time after the leaves have fallen, and without doubt some water is beneficial in assisting the plant to throw up its spikes of bloom. These Orchids are usually grown in a house with a dry atmosphere when they are in flower, and in houses of this description the plants often suffer for want of water at this season. Specimens with strong spikes which overhang the pots should be neatly staked, as no matter what purpose it is intended to use their flowers for, the spikes are better if kept in an upright position. Plants of choice varieties that have only made small, weakly pseudo-bulbs should not be allowed to flower, as flowers from weak plants are always unsatisfactory, and the benefit of resting the plants will be readily seen when they start into growth next season. The later flowering varieties, such as C. Regnieri, and some of the hybrids, should still be watered so long as the foliage remains green, gradually reducing the amount as the foliage ripens. As soon as the flowers are over the plants should be placed in their resting quarters, where they may receive all the light possible, but no water, and in a temperature which does not fall below 55°.

Chondrorhyncha Chestertonii.—This beautiful and interesting species is often classed amongst the difficult and troublesome Orchids, but recently it has been seen in better condition owing, chiefly, to its requirements being better understood. Doubtless the trouble in the past arose from the fact that the plant was grown in too much warmth, whereas it should be grown in a cool house, where air is admitted on all favourable occasions, and the roots never allowed to become excessively dry. This Orchid will succeed potted in a mixture consisting of equal parts of fibre and Sphagnum-moss, with plenty of small crocks and coarse sand added to render the compost porous. Potting may be done whenever the plant is throwing up new growths or developing fresh roots. During the greater part of the year the plants should be sprayed overhead and underneath the leaves, as a preventive against attacks of thrip and other pests.

Mexican Laelias.—These Orchids delight in more sunlight than most others, and during their growing season should only be shaded sufficiently to prevent scorching during the hottest part of the day. Fresh air should be admitted at all seasons whenever possible. The early varieties are opening their flowers; others are later, and by judiciously manipulating them the blooming period may be considerably extended. L. autumnalis and its variety alba. with L. albida and L. furfuracea are also in bloom. These need to be kept slightly cooler whilst making their growth, than the L. anceps section, whilst L. majalis should always be grown in the lightest position possible. When their flowering season is passed, these Laelias enjoy a good rest, and only sufficient water to prevent shrivelling should be given them. They should be grown in a night temperature of about 55°, and a comparatively dry atmosphere during the winter.

FIG. 99.—ODONTOGLOSSUM DESDEMONA II. VAR. RUBENS. R.H.S. AWARD OF MERIT, OCTOBER 30.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM DESDEMONA II. VAR. RUBENS.

THE illustration reproduced in Fig. 99 represents (reduced in size) part of the inflorescence of the pretty hybrid between Odm. Rossii and Odm. illustrissimum, for which Messrs. J. and A. McBean, Cooksbridge, received an Award of Merit at the Royal Horticultural Society's meeting on October 30. The hybrid is one of the most distinct of the thirty or so crosses with Odm. Rossii which has yet appeared, the sprays of flowers being elegantly displayed, and showing in a marked degree the claret red spotting on the sepals and petals which is a conspicuous feature in Odm. Rossii and the same lilac-pink tint on the lip which, however, is broadened by the influence of the hybrid parent. Odontoglossum Desdemona (ardentissimum × Hallii) was shown by Messrs. Sanders in 1914, and the second, now illustrated, which was shown in 1921, was inadvertently recorded, but distinguished as Desdemona II. The Rossii crosses are great favourites, being compact in habit, profuse flowerers and distinct from other classes of hybrid Odontoglossums.

LAELIO-CATTLEYA GOLDEN EAGLE.

THIS charming hybrid was raised between Laelio-Cattleya Luminosa and Cattleya Rex. The flower, which is of good shape, has golden-yellow sepals and petals, and the lip, which is crimped at the margin, is violet-purple, the extended lines of yellow from the base bearing evidence of the Cattleya Rex parentage.

ABNORMAL ODONTOGLOSSUM FLOWERS.

A STRONG spike of Odontoglossum of the O. amabile class with eight flowers, all of which are malformed in different degrees, is sent by Messrs. Sanders, St. Albans. Some of the flowers have the parts fully developed, but contorted so that the labellums are uppermost. One flower has the sepals nearly normal, but the upturned lip incorporates portions of the petals, the remaining parts not being produced. The column in each flower is abnormal and more or less divided, small petaloid blades being attached. The colour of the sepals is mauve with dark spotting, and the petals white with purple spots. The plant should be marked and its subsequent flowering observed.

CATTLEYA ARDENS.

THE first flower of this very brightly coloured hybrid between C. Dupreana (Warneri × Warscewiczii) and C. Hadyana (Dowiana aurea × Warscewiczii) is sent by Messrs. Sanders, St. Albans. Cattleya Warscewiczii in fine size and shape is the main feature, but in the labellum the rounder outline of C. Warneri and the deep tints of C. Dowiana bring great improvement. The sepals and very broad petals are bright violet-mauve, the exterior of the base of the lip being of the same tint. The front of the lip is deep ruby-crimson, and the disc chrome-yellow, changing to white on the side lobes. Thin purple lines extend from the base of the lip to the centre.

THE BULB GARDEN.

NERINES.

WHAT the Tulip is to late spring or early summer the Nerine is to autumn. Those who have never seen Nerines except at shows, or those who have only seen them in small numbers in a glasshouse, cannot realise what a sight it is to see a hundred umbels of Nerine sarniensis in full bloom in the open on a warm sunny autumn day—one glorious mass of shimmering rose, with ever-changing points of light glistening here and there. I have never done so; but I have enough imagination to realise that it must be something very wonderful and quite out of the common, even in that Nerine paradise—the favoured island of Guernsey—for even such an old inhabitant as my friend Mr. William Mauger must have been surprised, or he would not have taken the trouble to write and tell me about what he had suddenly come across in a small cottage garden. It no doubt came as a very welcome surprise, for no one mourned more than he the effects of the prolonged frost of 1895, when almost every Nerine on the island was killed.

Rose is not a popular colour nowadays, so perhaps it is a little difficult to realise the enthusiasm that the flowering of what I believe to be the same variety (sarniensis rosea) occasioned when for the first time European eyes saw it in "full blow" in the middle of the seventeenth century in the famous gardens of the Brothers Morin in Paris. No wonder General Lambert wanted to try it in his garden at Wimbledon. No wonder John Evelyn busied himself about its culture—please note, it was "difficult" then. No wonder Pére Rapin let himself go when he came to describe it in his celebrated poem on gardens:—

"Purple Narcissus of Japan now flow'rs,
Its leaves so shine as if with golden show'rs
It had been wet, which makes it far outvy
The lustre of Phoenician tapestry.
Therefore, t'augment the grace of France 'tis fit,
This flower into our gardens we admit."

The foregoing is from the translation by the famous Evelyn's son, which was published in 1673. James Gardner's translation is more enthusiastic. It appeared in 1706, and perhaps represents the increase in the fame of what had then become a much better known flower. It ends:—

"For should she but her conquering charms display,
From every fair she bears the prize away."

The true Guernsey Lily is, I believe, Nerine sarniensis rosea, described in 1729 as having flowers which, "in their prime, look like a fine gold tissue wrought on a rose-coloured ground." Alas! it is this fascinating beauty which has given the whole family a bad name. It is a shy bloomer in Guernsey itself—it always has been. I have read that in or about 1800 only from fifteen to eighteen bulbs would flower out of a hundred. About the middle of last century importations annually came from Guernsey. The bulbs were flowered once and then thrown away. Times have changed. Many will remember the choice exhibits staged from time to time at the autumn meetings of the R.H.S. by the late Mr. H. J. Elwes; those wonderful spikes from Oxford; the Bowdeni hybrids from Mr. Peter Veitch, of Exeter, and the displays of Messrs. Barr and Sons. Whence came all these new varieties I do not know. More than one species must have gone to their making, but as Mr. E. H. Krelage once said at a Horticultural Club dinner when questioned about the origin of the Darwin Tulips, which for so long remained a mystery, so must I say about the present race of hybrid Nerines: "It is sufficient that we have them."

These notes are written with the object of trying to persuade those who have room in glasshouses to "go in" for them. A neighbour three miles away has at the present time one empty glasshouse. In pre-war days it was a warm greenhouse. There are probably many who have suffered somewhat in the same way. All that Nerines ask in the way of heat is to be kept free from frost. So if what once were stoves and warm houses could be turned into cool houses, Nerines are among the subjects which the owners might grow. The newer varieties are far more free flowering, and as my own records show, there are some that may be counted upon to flower every year or twice in three years if only the simple requirements of the race are duly carried out. The two great essentials are care of the foliage and mild feeding with a weak liquid stimulant during the winter months, and a thorough drying off and baking from the time the leaves turn yellow until the beginning or middle of September, when the dormant bulbs begin to show us they are alive by putting out their little, sharp-pointed "tongues." Water may then be given. As the bulbs do best if they are allowed to remain without repotting for three or four years, I have found nothing better than virgin Kettering loam, with the addition of a fair quantity of silver sand and some dried and pounded cow-dung as a potting compost. They should be only half buried in the soil, as this allows their dry and loose outer coats to be removed when growth restarts in the autumn.

I have had several discussions with the late Mr. Elwes about the advisability of doing this. The conclusion we came to was that it ought to be done. My war experience has confirmed the benefit of this treatment.

The one great enemy of Nerines is mealy bug. So long as I had labour sufficient to strip the bulb coats off every year, never a pest did we see. After three years of neglect we had a visitation, which I am glad to say we have managed to conquer by taking heroic measures. The first outward and visible sign of the little pests is white marks on the foliage, which look just as if there was a small suspicion of lime in the water with which they are watered. It is then time to examine the base of the leaves and the roots closely. In our case we did little but pick the insects off; but in July, when the bulbs were dormant, every potful was turned out and all the worse cases burnt. If only two or three bugs were found the roots were carefully washed and all the loose outer coats of the bulbs taken off, and the latter repotted. The next growing season, hand picking was vigorously followed, with the pleasing result that we have now quite got the better of the pest. We have found an invaluable ally in Garner's Nicotine Wash, with which we water the foliage. It seems to reach the pests among the lower interstices at the bases of the leaves, where fingers are of no avail. By this means my collection has entirely regained its fine, healthy, pre-war condition. I have seen mealy bug in both large and small collections of Nerines; in some cases in considerable numbers, while in others there were only very few.

I would like to say something about the best varieties, but I have come to the conclusion that with a few exceptions names mean very little. Messrs. Barr and Sons, who make a speciality of them, list about a hundred varieties, but I recognise very few, although it is likely I have exactly the same under another name or with just the description of the cross on the label, inasmuch as we both had a great many of our bulbs from Colesborne.

Of those that I know, I would recommend for a start N. Fothergillii major, an early flowerer with large scarlet and orange-red umbels, and N. sarniensis corusca, a dwarfer grower with smaller umbels and flowers of a beautiful soft salmon-red. The description in Barr's catalogue as "a brilliant, fiery orange-scarlet" must refer to one I have as corusca major, which in turn is similar to Meadowbankii and Miss Willmott. Lady Mary Shelley is a good pink with a rosy centre, similar to and, I think, finer than, Miss Shelley. It is one of the freest to bloom. Lady Bromley is a curious blend of rose and a deep blue-mauve, one of the freest to bloom, and a lady's favourite. I have had it for many years, but it seems more like Barr's Miss Cecily Elwes than their Lady Bromley. The practical politics of this uncertainty of names is either to trust the seller or to go and pick out the varieties while they are in flower. The best time to buy is when the bulbs are dormant. The next best is immediately after or during their flowering. In this latter case the purchaser can himself see that the treatment of the plants is what it should be from start to the finish. *Joseph Jacob.*

CAMASSIAS.

THESE attractive and graceful North American bulbous plants are very valuable for June flowering, and should be planted as early as possible in November. Although beautiful in the border while in flower, they are apt to become untidy afterwards, and the ideal place for them is a partially-shaded glade of the woodland, where they may remain undisturbed for years. C. Cusickii is a handsome species forming a rosette of broad, glaucous leaves, and throwing up tall, elegant spikes of large, pale lavender flowers with yellow anthers.

C. Leichtlinii produces tall spikes of starry, creamy-white flowers with pink anthers.

Two garden forms of C. esculenta, Royal Purple and Silver Queen, also produce handsome spikes of dark blue and light blue flowers respectively, and are well worth growing. When left in the same position for several years they should be given an annual top-dressing of rich compost, and as soon as signs of exhaustion appear they should be lifted and divided. *W. Auton.*

NOTES FROM A WELSH GARDEN.

THE most delightful plant in flower in our woodland garden during these autumn days is Polygala chamaebuxus. The dark green, leathery foliage of this little creeping shrub is cheerful at any season, but when the plant is covered with blossom, as it is for so many weeks in succession, both in spring and autumn, it is singularly attractive. This is a very variable plant, some forms being much broader in leaf and larger in flower than others, and though the variety purpurea is deservedly more popular than the type, there is room for both. Whether the beautiful P. Vayredae is simply a geographical form of the above I do not know. It has narrower leaves than any forms of P. Chamaebuxus which I have seen and is not nearly so robust with us.

Although I am writing at the end of October, the Heath slope is still full of colour, the most noteworthy groups being those of Erica ciliaris, the somewhat similar E. Watsoni (tetralix × ciliaris), E. Maweana, and E. cinerea atropurpurea. This last is later and dwarfer than rosea, and in both colour of blossom and stature comes between that fine variety and the gorgeous little E. c. coccinea, which is still quite gay. This beautiful dwarf Heath is the only one of its race known to me which has any orange in the coloration of its flowers. But the rich crimson-scarlet of its "bells" shows a distinct trace of that colour just before the corollas fade.

At any other season the russet hue that now dominates the ranks of E. vagans, as the long racemes of blossoms at last become spent, might be considered unsightly. But the red-brown of these withered flowers blends very happily with the tints of autumn, and with such blossom colour as still remains among the Heaths in general. Worthy of note also is the warm coppery hue which at this time of year returns to Calluna vulgaris var. cuprea, and hardly less attractive is the deep gold of the var. aurea.

Down by the water, where the handsome foliage of Galax aphylla and the Shortias is being touched with the "hectic red" of autumn, some Gentians of the asclepiadea set are still as fresh as ever, the pale luminous blue of Perry's Blue being especially lovely. Here also are several happy colonies of Cyclamen neapolitanum, whose rosy-carmine affords patches of colour of an unusual but not inharmonious note among the prevailing yellows and duns of fallen leaves. Omphalodes cappadocica brings a sheen of springtime azure to a half-shady bed by the stream-side, where the tall fronds of Osmundas and the large round leaves of Saxifraga peltata are aglow with

Digitized by Google

tawny yellow. Also hereabouts, draping the mossy stones along the margins of the paths, the pretty foliage of Tiarella cordifolia is stained with those bronze and crimson shades for which this charming woodland plant is so well known and appreciated.

Fragrant flowers being uncommon at this season, some clusters of blossom on Daphne Dauphinii (hybrida) are especially welcome. Another lowly shrub which has broken into a second blooming almost as liberal as the first is Rosmarinus prostratus, one of the most delightful of rock-garden evergreens. This year it promises (weather permitting) to keep in colour until Lithospermum rosmarinifolium, which occupies the same dry, sunny ledge, opens its wonderful flowers. Here also is Lavendula dentata, throwing up a late crop of long, lilac-tipped bloom spikes which are hardly likely to achieve development. At best they are not so attractive as those of the Common Lavender, but the foliage of L. dentata easily excels the latter and all its varieties in the important matter of fragrance.

Still showing their bright fragments of colour are Salvia Grahamii and S. Greggii, and always among the latest bloomers are the shrubby Veronicas of the Andersonii group. These are not really hardy here, even in a sheltered spot, and their attractions do not appeal to me personally. The silvery V. Andersonii variegata is welcome enough when it gives a display of its long, flue-brush flowers in a pale violet blue when we are nearing winter, and there is a decided charm about Mt. Blanc, with snow-white blossoms against dark green foliage. But a white Veronica of more distinction which we like better and which flowers earlier (July-November) is V. macroura. This is a semi-prostrate shrub, with large leaves and curiously curled, cylindrical spikes, densely set with white blossoms. This is a good deal hardier than the above varieties.

Two hardy Geraniums are interesting just now. One of these is G. atlanticum, whose round, deeply-cut leaves are appearing in a fresh spring green dress, the plant having been quiescent since summer. The other is G. anemonaefolium, which at this season establishes its right to be regarded as a foliage plant of much merit. Unlike the former, this Madeiran species never "rests" at all, for as soon as the last of its beautiful flowers are passing it commences sending up its large, palmate, fleshy leaves on their stout, rigid stems, and this handsome foliage will not cease growing, save during cold spells, throughout the winter. *A. T. Johnson, Talycafn, N. Wales.*

TREES AND SHRUBS.

PYRUS MALUS GIBBS'S GOLDEN GAGE.

Pyrus malus Gibbs's Golden Gage is one of those come-by-chance hybrids, like Cox's Orange Pippin, which can never get into the stud book as no one can do more than guess as to its pedigree. Nevertheless, like most hybrids, it is a fine, robust, vigorous plant, with foliage and blossom very like those of the typical Apple tree. Its outstanding merit consists in the fruits, which are very freely produced year after year. These are egg-shaped, and about the size of a bantam's egg; in colour they are of a bright clear yellow, faintly flushed with red, moreover, their surface is waxy and translucent, so that when the sunlight catches them they look almost as if one could see through them. There is one last advantage that ought to be credited to this variety, that as late as November 3, when this note was written, not one of the Apples had yet fallen, although all other fancy Crab trees had shed their fruit, and some, like "Beauty of Montreal," did this more than a month ago. *V. G., Aldenham.*

FREMONTIA CALIFORNICA.

There are few more handsome wall plants than this Malvaceous shrub. Its orbicular, bright, shining green leaves and clear yellow, bowl-shaped flowers, often three inches across, with orange stamens in the centre, make it an object of striking beauty. Its season of flowering is early summer, but it often remains in bloom for months, and a young specimen in these gardens is now (October) still carrying flowers.

The plant thrives in light, sandy soil, and soon attains a height of 8 feet to 10 feet, but it does not appear to live to a very great age. It is, however, readily propagated by means of cuttings of the young shoots inserted under a bell-glass, or seeds may be sown in sandy soil in a cold frame in spring.

CISTUS.

The members of the genus Cistus possess a brightness and charm all their own, and although the individual flowers are short-lived, they are produced in such abundance and in such quick succession that a fine floral display is continued over a long period.

These elegant shrubs, or sub-shrubs, are natives of the Mediterranean region, and should not be placed in exposed or wet positions, but most of them will withstand our

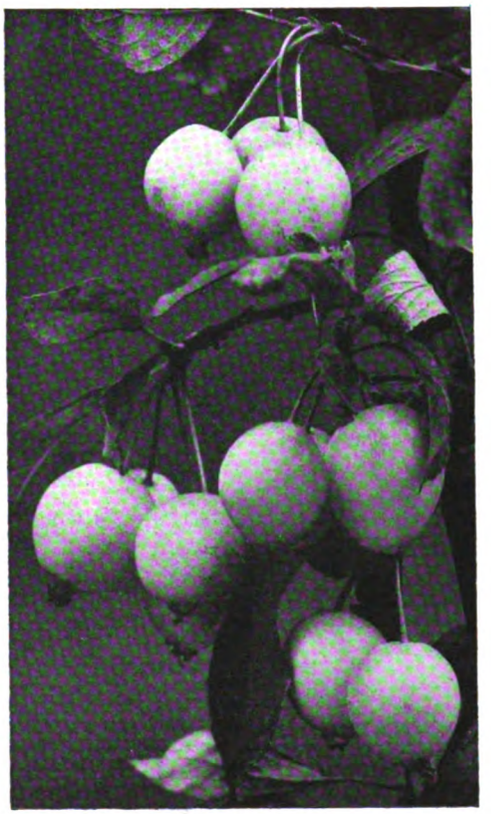

FIG. 100.—PYRUS MALUS, VAR. GIBBS'S GOLDEN GAGE.

winters in the southern counties provided they are planted in freely drained soil. They are especially valuable for the wild garden, and seem to love places despised by other plants, for no soil seems too poor and no position too dry or sunburnt for them, while for quickly clothing dry, sunny banks they are ideal.

The Cistuses delight also in a groundwork of Heather, and a beautiful effect may be obtained by planting some of the taller varieties in free, carpet-like masses of Heaths.

C. ladaniferus, one of the finest members of the genus, has large white flowers with a bold, crimson blotch at the base of each petal. Its leaves are deep-green above and silvery-white beneath, and the leaves and stems exude a resin which has suggested the name of Gum Cistus. C. laurifolius is a tall grower, very hardy and easy to grow. It has a good habit and lasts for many years, producing its white flowers with yellow markings throughout the summer.

C. cyprius is a beautiful species, producing flowers 3½ inches wide of the tenderest white, with a red-purple blotch at the base of the petals. C. florentinus is a good grower and quite hardy. It has wrinkled leaves and large white flowers with yellow base. C. hirsutus is a low-growing species, with oblong, blunt, hairy leaves, and white flowers with yellow base. C. monspeliensis is a compact grower, with medium-sized, white flowers and dense foliage. C. purpureus is a very beautiful kind, with neat, erect habit, pale green foliage and reddish stems; the flowers are very large, rosy-purple, with darker spots at the base of each petal, and they continue in succession till quite late in the summer.

C. formosus (syn. Helianthemum formosum) should be included in this group, as it gives variety in colour. It has hoary foliage, and bright yellow flowers with bold black markings. C. immaculatus is somewhat tender, and should be given a very sheltered position. Where such can be provided it is well worth growing, as its magnificent white flowers are most attractive.

The propagation of Cistuses is easily effected by cuttings or seeds. Cuttings of half-ripened wood, inserted in sandy soil in August, and given the protection of a bell-glass or cold frame, root freely, and may be planted out the following spring. Seeds may be sown in early spring, in a cold frame, where they germinate in a few weeks. When ready, the seedlings should be potted into 3-inch pots, from which they should be planted into their permanent positions, as they dislike transplanting. *W. Auton, Pyrford Court Gardens, Woking.*

PIERIS FORMOSA.

Few will deny this fine shrub its claim to be the most beautiful member of its genus, its only drawback being that flowering early, and a little tender, its buds and blossoms are apt to be injured by frost. Nevertheless, it is quite hardy enough for almost any of our more favoured westerly and southern counties, where it has the reputation of being a robust, long-lived subject.

P. formosa is usually seen as a bushy shrub of 8 feet to 10 feet in height. Its ample evergreen foliage consists of handsome, lanceolate leaves, often 6 inches long, of a dark, burnished green, and firm in texture. In autumn the flower buds appear in bold reddish tufts at the tips of the branches, the blossoms opening in May or earlier, according to weather and locality. These latter are large, pure white and urn-shaped, and they are disposed in elegantly arched, or drooping, panicles some 5 inches to 6 inches in length. Then, when the flowering season is over, the new growths appear, and these being a bright, glossy vermilion, and eminently graceful, they constitute no small part of the attractiveness of the species.

This fine shrub is by no means difficult to grow in a suitable locality. It doubtless enjoys peat and leaf-mould, but it will prosper in any well-drained, lime-free loam, and in such established specimens have been known to carry on for years without any attention beyond perhaps a mulching to prevent undue evaporation at the roots.

ERICA CILIARIS VAR. MAWEANA.

This handsome Heath may claim to be the finest of all the later flowering kinds, but though discovered in Portugal nearly fifty years ago by the late Mr. George Maw, it has never become common in gardens. This is the more difficult to understand when one realises that it is as robust and hardy as the type species (Dorset Heath), itself among the best of the species, and it is, moreover, quite distinct.

Compared with E. ciliaris, this beautiful Heath is more upright in habit, its foliage is a darker green, being less hairy, and the flowers, borne on stiff, erect racemes, are, individually, about half an inch in length, and a full-toned, rosy crimson. E. Maweana will prosper in any good lime-free loam and leaf-mould, or sandy peat, in which other Heaths grow. It is desirable, however, to give this variety—and others of the ciliaris group for that matter—a sheltered place, since they dislike wind. Being late in flowering, they are likely to get not only rougher weather but less sun than the earlier Heaths, a fact to be kept in mind when planting. *A. T. J.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 5, Tavistock Street, Covent Garden, W.C.2.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS**, 5, Tavistock Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

SOME OLD SCOTTISH PLANT NAMES.

SCOTLAND produced no Herbals, and its old plant names must be sought for elsewhere. The earliest book one would expect to find such names in is one published two and a quarter centuries ago, entitled *The Poor Man's Physician*, by W. Moncrieff, of Tippermalloch, commonly known as Tippermalloch's Receipts. But Scottish plant names are singularly absent from its pages, and I have to thank two perfervid Scots who owned sixteenth-century Herbals for inscribing in the crabbed caligraphy of the period the Scottish names of the plants therein. Some of these names are long ago obsolete, some have to be searched for among French names, while most are still doing duty in Scotland.

They are interesting on another account, inasmuch as quite a number of old Scottish plant names are not mentioned at all, due, perhaps, to the localisation of these even so long as three centuries ago. Nothing can be more expressive than some of these long-forgotten vocables. There is, for instance, Gritt Stonie Thirl. "Thirl" exactly defines the way Stonecrop, the plant in question, attaches itself to the stones on a dyke. To be "thirled" to anything or anyone means to be completely and absolutely attached thereto, just as the people on an estate were thirled to the mill on the property. There and nowhere else dared they send their corn to be ground into flour. Sneezing is given for Achillea Ptarmica. The name occurs under another herb as Neesing Powder, which is quite good English, as a reference to the Book of Job demonstrates. The herb was reduced to coarse powder and snuffed up the nostrils to induce sneezing in order to clear the brain of noxious humours! Later, when Nicotiana displaced all other herbs as a snuff, the Scot still continued to call the powder of that titillating herb "Sneishin."

Under Galium verum is Chesewort, a name that associates that pretty herb with the production of cheese, a decoction having been employed to coagulate milk when a calf's stomach was unavailable for the purpose. Chesbow, another old name, is distinct, and distinguished the Poppy, as in the *Eneados* of Douglas. There are two Purpies noted, the garden and the wild. These names long maintained a place in the Scots vernacular for Purslane, and are the French Pourpier. Brooklime was known on the Borders as Water Purpie, and all three were eaten raw or in salads. Foxglove in one Herbal is named Fuller's Thystell, not improbably in mistake for Dipsacus Fullonum. In the other, Foxtrie is the name, and this is found elsewhere as Foxter-leaves. Even at that period Digitalis had its physical uses, having been given to sick children, some think, for convulsion fits, but so far there is no assurance that that was the complaint. Anyhow, the mothers who were caught using it were subjected to ecclesiastical censure and forbidden its use. Why is also obscure, and most probably owing to the impression that the Good Folk or Fairies had a strong attachment to the plant, the ministers may have thought it necessary to check any intercourse, however well-meaning, with that shadowy people.

We come on another French name in Rayfort, which long kept its position in colloquial Scots, and it is Robert Chambers who, I think, mentions Raiforts being cried by the women of his day who hawked vegetables in the streets of Edinburgh. Though in France the name included Horse Radish as well as Radishes, the latter were those only that were so-called in Scotland, and it is not a little interesting that someone, when Mary Stuart was queen, should make a note of its being then a name current in her country. One would be dubious about the French Marigold being cultivated at that period, but it is recognised by the unknown scribe as "Tansie of India." Names that are still familiar in Scotland are Fou for Sempervivum tectorum, though it is more usually called Fouats; Mylds for Atriplex hortensis; Bourtrie for Elder; and Blewe-blawe-wort for Centaurea Cyanus. Some names seem to have been guesses. Such are Englyshe Rubarbe for Veronica Chamaedrys; Cucu pintill for Polygonum Bistorta; Wyld Beets for Pyrola rotundifolia; and De Netell for Urtica "romana." There can be no mistake regarding the identity of these and other plants, for the names are all inscribed under their figures Flaergras for Galium Aparine and Phuonole for Nepeta Glechoma are, however, names that I do not understand.

Even earlier than the above are a few more. Catcluke is one. The last syllable defines a pronged implement for dragging, and the plant may be Lotus corniculatus or one of the associated plants, which, when in seed, has the appearance of that implement in miniature. Earlier still is Jonet, "the Jonet Swete of smell" and "floure Jonettis." Quite obviously these are the French Jonette, and the flower they represent is either Narcissus biflorus or another of that genus. While, however, the French name continued long in use, the Scots one must have lapsed very long ago. Not so late as any of the above is the strange-looking name Doudlar, the Phragmites communis, which, however, has become obsolete. It recalls a time when the country lad of musical affinities had to solace himself with a sort of Pan's pipes composed of the old stems of this grass, and the playing of this simple instrument was called "doudling," a designation somewhat similar being still employed to describe bagpipe-playing. "Tootle" is, no doubt, another form of the word. Of less age, for the same plant is the name Bog-reed, applied to the same musical instrument, and also to another composed of a single reed and the shank-bone of a sheep.

One might dilate on the names, now out of use, of vegetables—the Bowkale, applied to Cabbage, meaning short-stemmed; another sort the Langkale Greens, not as in England, applied to winter stuff generally, but to the Scotch or Curled Kale. Then there was the Costie, in various ways of pronouncing the word, but all descriptive of the pith of the Cabbage stock, which was eaten as a delicacy by bygone generations of Scots. The name is directly from the Latin *Caulis*. The stock or stem itself was a Kale Runt. Not long gone out of use is Syboe for young Onions. This also has a Latin derivative—*Cepa*. I will only further mention the curious circumstance of the Turnip being regarded as a fruit, a fact that Sir Walter Scott enlarged upon in *Rob Roy*! The reason, no doubt, was that young Turnips were eaten like Radishes, the number of instances noted by writers, novelists, travellers, and horticulturists, proving that the custom was quite common well into the eighteenth century. *R. P. Brotherston.*

WOUND DRESSINGS.

THE importance of protecting wounds in trees, whether caused by sawing off large boughs or by the heavy pruning of second year or older wood, is becoming more and more recognised; *Market Grower* refers to some protecting agents that have been tried (p. 223), and perhaps I may be permitted to add others.

The most useful preparation that I have tried is what we call "sulphur oil"; my first trials were made in 1912, and it has been in use ever since, not only by myself but by several friends to whom I have distributed it. Small canker wounds have healed entirely, and larger ones have ceased to increase under its use; moreover, as an application for American blight it has been found that renewed attack at a site is rare during the same or a second season after one application; put with a brush on the colonies, it is my standard antidote for this pest. Where boughs have had to be sawn (mostly from breakages due to undue weight of Plums), the cut surface rough from the saw is treated; when crown grafting on larger wood, only the site of the grafts is smoothed with the knife, and their neighbourhood only waxed, the remainder of the surface is left rough and given a smearing of the sulphur oil. In treating canker, nothing is cut away—against the stock advice; if there is much chippy dead bark, it is rubbed off a bit with the hand, plenty of scaly bits being left to make a binding.

The preparation is founded on the *rasolimentum sulphuris* of pharmacy, and is prepared by thoroughly boiling linseed oil with sulphur (preferably flowers of sulphur) and stirring occasionally; the prescription gives the proportion of 3 of sulphur to 37 of oil, that is, about 8 per cent. by weight; a larger quantity of sulphur will not combine, but crystallises out on cooling. As some smell is evolved in the boiling, it is best carried out in some outbuilding. Care should also be taken that the vapours do not ignite. It is essential that the boiling be carried on to complete dissolution of the sulphur; the fluid then has the dark colour of Stockholm tar, but is more fluid.

For use, this stock solution is generally diluted with some 9 parts of linseed oil. When dabbed on in patches, even on young shoots infested with Schizoneura lanigera, I have never known any harm accrue; but I may add that a friend's gardener thought to tackle mealy bug with it on an indoor vine, and painted the whole rod freely with it. As seen a month or so later, the vine evidently did not like it, but I do not know whether it eventually recovered. Anyhow, it was too heroic an application. From its fluidity the preparation does not make a visible varnish, though protection seems to be good notwithstanding. No doubt the lubricating or softening effects of the oil promote healing of hardened bark, and the mere fluidity must help to promote soakage into deeper parts. With a view to making a more varnish-like preparation, a compounding of rosin with sulphur was made; the rosin or colophonium was found to take up about 20 per cent. of sulphur, but somehow the results obtained with the plain oil method have been so good that the rosin-sulphur-oil has not been used very much. Still, it offers a field to experimenters who wish a more varnishy product. Cacao-butter will take up about 20 per cent. of sulphur, and might be thinned with oil; beeswax also affords a compound, neither of which has been actually used yet.

It may be added that mineral oil, e.g., *paraffinum liquidum*, will combine to a dark fluid with sulphur, but ordinary paraffin oil (burning oil) merely dissolves it with crystallisation on cooling. Probably the boiling point is not high enough to engender combination.

Though another line of business, I may add that these preparations were also tried as emulsions for spraying in 1912; a note before me in July of that year gives a mixture which

Digitized by Google

was tried on Roses of rosin-sulphur-oil dissolved in plain oil and emulsified with soap and gelatine. How long it has taken for the popularisation of "spreaders," as they are now called! And yet in France their importance (gelatine, quillaia and sapindus saponins, etc.) was known many years ago.

In another series of substances copper was selected as the fungicidal agent, but there was some difficulty in getting satisfactory solutions of some products. Copper carbonate was heated with twice its weight of colophonium; the resulting "resin soap" dissolved best in rosin oil; alcohol, even hot, refused to take it up. This, with some dilution with linseed oil, was used as an application to cut surfaces on three indoor vines, as it was noticed that these points showed much sporing mildew; possibly the varnish alone would not be without effect. Other copper soaps, prepared by precipitating soft soap with copper sulphate, were made. One preparation showed about 6 per cent. Cu (n.b. Cu stearate contains 10 per cent.). Here again the solvent question gave trouble, and on the whole, rosin oil seemed best for the purpose of solution. Such preparations were tried both as varnishes and as emulsions for spraying; no damage was noted.

In the form of watery applications, some chinolin or quinolin compounds were first tried about the same year (1912). These were founded upon Cazaneuve's vine spray (1912), consisting of chinolin-(2), pyridin-(1), mixture 200 grams, copper acetate 1 K.000, water 1 Hl. I fancy that one of the chief uses of the pyridin is to get more solution of the chinolin As a spray, the absence of scorching was noted, but the knowledge of copper-sensitive varieties was not known in those days. In 1917 a Plum tree (Impériale de Milan) was moved from where it had grown since 1899; it started gumming very badly, and looked altogether decrepit. In 1918 the branches and trunk were somewhat laboriously painted over with a fairly strong mixture of the above formula. Later they were hand-smeared with clay to close the apertures through the bark; last year it was sufficiently well to bear a couple of fruits.

Brooks has lately tried quinoline compounds (*Journ. of Pomol. and Hort. Sci.*, vol. III., 1923, p. 133). He found superol, otherwise known as chinosol, and consisting of oxyquinoline sulphate, to be the most efficient fungicide for stereum. Besides quinolin, other bodies such as aniline have been tried, but my notes are too scanty for reproduction. But I may more especially allude to nitrobenzol (oil of Mirbane), which is so largely used as a preservative in pastes, shoe-polish, etc.; it is rebellious stuff to emulsify, which is perhaps best done by preliminary solution in oil and subsequent emulsification with soap, and rather dangerous on leafage when not well emulsified, but it has insecticidal powers as well as fungicidal. It is now too late for trial this season, but I would commend wrapping a piece of wadding round a thin stick, moistening it with say half a teaspoonful of the above compound, and thrusting it into the entry hole of a wasps' nest and stamping down the aperture. By its aid, the use of cyanide may perhaps fall into oblivion, even on a waxing moon (which, I am told, is no time for taking wasps' nests, "as the grubs will continue to hatch"). Next day it is safe to dig out the nest. Naturally, the use of vapours in houses may be thought of. Nitrobenzol, as well as chinolin, has also been added to the "sulphur oil," but I am unable to say whether it has been advantageous. *H. E. Durham.*

The Hay Crop.—According to the returns of the crops for 1923, compiled by the Ministry of Agriculture, the yield per acre of Meadow Hay, 22.3 cwt., was also above average, being about 1½ cwt. per acre above the decennial mean, and 4 cwt. per acre heavier than in 1922. The total production of 4,865,000 tons is 800,000 tons greater than last year. Taking both kinds of Hay together the production is estimated at 7,693,000 tons, compared with 5,789,000 tons last year and 5,339,000 tons in 1921.

PLANTS NEW OR NOTEWORTHY.

BUDDLEIA AURICULATA.

Being a native of South Africa it is not to be expected that this shrub will be really hardy anywhere in the British Isles except in the south-west and similarly mild localities. It will, nevertheless, survive mild winters, such as that of 1922-3, even near London. The plant at Kew from which the branches shown at the R.H.S. meeting on October 30 were cut (fig. 101) is growing in one of the recesses in the outer wall of the Temperate House. There, although facing east, the building gives it a certain amount of protection. A severe, or even moderately severe, winter will no doubt kill it to the ground.

FIG. 101.—BUDDLEIA AURICULATA. R.H.S. AWARD OF MERIT, OCTOBER 30.

The flowers are pale pink with a slender downy tube ¼ in. long and are crowded on short panicles, both axillary and terminal, the whole forming a leafy inflorescence 1 ft. to 2 ft. or even more long. The leaves are lanceolate, sparsely toothed towards the slender points, dark green above, glaucous beneath, and 1½ in. to 4 in. long. In habit the shrub is loose and graceful, and will grow 10 ft. or probably more in height. The fact that it blossoms in late October and November adds much to its value; still more does its charming Primrose-like fragrance.

Mr. Reginald Cory grows Buddleia auriculata in his garden at Duffryn, near Cardiff, where it is likely to be almost permanently safe from destruction by cold. He states that its fragrance is perceptible several yards away. Like all the Buddleias it grows well in loamy soil and is easily increased by summer cuttings placed in gentle bottom heat. *W. J. B.*

PRUNUS DIELSIANA VAR. LAXA.

This Cherry is still rare in gardens, although it has been in cultivation for a number of years. It was introduced by Mr. E. H. Wilson from China during his 1907-09 expedition. The collection number is 37, and this Prunus was found at the same time as Prunus Conradinae, P. tenuiflora, P. pilosiuscula and the varieties media and barbata, but is absolutely different from them all. It is the last to flower, and terminates the flowering season of the group.

I have every reason to think that this Prunus will thrive and the trees make very good specimens. The young wood is smooth and polished; the leaves are rusty hairy beneath, with a somewhat rough upper surface. The foliaceous bracts are margined with stipitate glands and are very conspicuous; the pink flowers are crowded on spur-like growths at the beginning of May. So many glands present may tend to mar the beauty of this Cherry if grown in the environs of smoky districts, as the sooty particles will adhere to the sticky secretion. At the time of writing the bronzed red and yellow colour of the foliage commands attention. *C. F. C.*

THE ALPINE GARDEN.

ANDROSACE.

GIVEN free drainage, a light porous soil and a little protection under certain circumstances against wet and foggy weather, most of the Androsaces are quite easily managed. Such species as A. sarmentosa, A. s. Chumbyi, A. Chamaejasme, A. lanuginosa, A. l. Leichtlinii, and A. sempervivoides, are quite happy when planted in the crevices and interstices of rock-work or on rocky ledges; if in an almost perpendicular position, so much the better, for then protection against damp may be dispensed with.

A sandy and gritty loam is the best rooting medium, for very few of these high alpine plants, of which A. carnea is the best known, are peat-lovers. When they are grown in such a position as to be quite unprotected from rain and fog, sheets of glass raised a few inches above the plants will bring them safely through the winter. This protection should not be afforded until it is absolutely necessary, certainly not earlier than November, and should be dispensed with as soon as possible in the spring.

A surfacing of chippings is always advisable, and full sunshine is, of course, a great necessity. A. foliosa, the strongest-growing member of the genus and very near to Primula, is a fine plant and an "easy doer." A few of the smaller-growing species are rather difficult plants, and should be grown in the moraine; these include A. pyrenaica, A. helvetica, and A. (syn. Douglasia) Vitaliana.

A geraniifolia, a species of comparatively recent introduction, is quite distinct from the other members of the genus, and not so attractive as many of them; it is very easily grown. Some other excellent species are A. tibetica, A arachnoidea, A. villosa, A. primuloides, A. brigantiaca, and A. ciliata.

All the Androsaces are excellent subjects for the Alpine home, grown either in pans or planted out, and when grown under glass the small flowers are very bright and of pure colour.

Propagation is best done by means of seeds, and these, as in the case of the nearly-related Primula, should be sown when they are quite fresh. A. geraniifolia may be propagated by means of runners, which it produces much in the same manner as does the Strawberry. If pegged down the runners will root quickly and easily. The essentials in the successful culture of Androsaces may be summarised as: a maximum amount of sunshine, free drainage, a light, gritty soil, and immunity from stagnant moisture about the roots and from stationary moisture on the rosettes, when the species take this form of growth. *Ralph F. Arnold.*

ERODIUM CORSICUM.

THERE are few more charming rock plants than the Erodiums, or Herons' Bills. It is not easy to select among so many good little plants, and to assert that the one chosen for notice is the best. Nor, were I compelled to select one or two out of the race and say that these were the most delightful, would I, perhaps, include E. corsicum and grow it to the exclusion of most of the others. As a plant it does not seem to be so dowered with subtle refinement as some others, but it has a good claim to be reckoned among the best half-dozen of the family. It has the merit of succeeding in a dry, sunny, calcareous, well-drained soil, and, if allowed plenty of room, will grow into masses with charmingly formed, scalloped and crimped silvery leaves, which are quite downy in appearance. The plant will spangle the carpet thickly with rose-pink flowers, whose beauty is heightened by the deeper colour of the veining, while the flowers, unlike those of some of the other species, have all the petals of the same size. The plant makes a beautiful carpet, and a good-sized one, such as has been seen this summer in the Royal Botanic Garden, Edinburgh, has an unspeakable charm indeed. Its specific name of corsicum is not so inappropriate as that of some other plants with geographical designations, as it comes mainly from Corsica, although it is also a native of Sardinia. *S. Arnott.*

PUDLIC PARKS AND GARDENS.

THE Manchester Public Parks and Gardens, under the superintendency of Mr. W. W. Pettigrew, occupy a very important place in the municipal activities of that great city, and progress is being continually made both in adding to the City's open spaces and in the providing of new features and attractions in existing ones. The great use to which the Manchester Parks are put for the purposes of recreation is shown in the receipts from games in the half-year ending September 30. They are as follow: Bowls, £2,827; tennis, £3,981; boating, £3,606; golf, £2,111; putting green, £33; hire of chairs and sale of programmes, £1,117; and catering, £7,617. The total income for the half-year amounts to £21,293 19s. 10d., which is slightly below that of 1922, when the receipts were £21,592 7s. 3d.

A much larger income would have been derived from these sources but for the unfavourable weather, for, to cite an instance, rain fell on one hundred out of one hundred and fifty-three days on which the bowling greens (exclusive of Sundays) were open for play.

As is well known, inhabitants of towns in the Midlands very much appreciate good music, and the concerts provided in the various parks have been well attended by the townsfolk. The number of concerts given during the season was 417, embracing 341 of an instrumental and 76 of a choral nature, and they were rendered in thirty-seven parks and recreation grounds, including two school yards. The number of bands and choirs engaged was fifty-three.

Recreation for children is well catered for in the Manchester Parks, and provision is made for children's dancing, Punch and Judy performances and sand gardens, in which the juveniles find great delight; indeed, it is stated that during the season no fewer than 49,208 boys and 50,419 girls, making a total of 99,627 children, made use of the sand gardens. It is interesting to know that the children appreciate the dancing, which is organised by a lady supervisor, and a large number of adults find considerable interest in watching the children dance, thus providing pleasure for young and old alike. As in the case of the other outdoor sports, the dancing was affected by the unfavourable weather, but it is satisfactory to learn that well over 20,000 children attended the dances.

Perhaps the most novel of the attractions is that of providing the youngsters with Punch and Judy performances. These were given by three "professors" in twelve recreation grounds and one park on special afternoons and evenings during August. As showing how this form of amusement was appreciated, it is stated that as many as one thousand children were frequently present at a single performance of "Punchinello."

One or two special features have been introduced in the Manchester parks during the past half-year, including an indoor gymnasium for small children at St. George's Park, and an eighteen hole putting green at Heaton Park, and so successful have these been that it is probable they will be instituted in every park and open space where favourable conditions for their introduction exist. The laying out of the putting greens will provide work for unemployed men during the coming winter.

The share of the parks department in the City's scheme of providing work for the unemployed is seen in the following works which have been completed in the parks during the past six months:—The forming of shale tennis courts in twelve parks and recreation grounds; the construction of six bowling greens; path renovation in fourteen parks, playing fields and cemeteries; the construction of new paths in three parks; the drainage of football fields; the alterations of band stand enclosures; the removal of hedges; the construction of a promenade in Heaton Park; the making of golf putting greens in Heaton Park; the construction of a paddling pool and children's playground in Heaton Park, and the formation of a model yacht pond in Whitworth Park.

THE RELATIONS BETWEEN HORTICULTURE AND PHYTO-PATHOLOGY.*

(*Continued from p.* 265.)

SOME diseases interfere with flower breeding. The mildews of our flowering plants are good examples. They do not live on the seed, very often their hibernating places are unknown to us, and especially is this so with those mildews of which we never or seldom find the perithecia. They may only be controlled by measures applied to the plant directly. I have in view here the mildew of the new varieties of Delphinium. We see the tenderest colours affected in midsummer by the common mildew, Erysiphe Polygoni, which not only affects the leaves, but also causes deformations of the inflorescence. Breeders will be obliged to consider this white pest when raising hybrids and making selections. It is obvious that there is an increased susceptibility, and that ancient strains were most resistant.

A scientific study of the genetics of mildew-susceptibility has been made by Klaphaak and Bartlett, on account of the mildew of Œnotheras. They found immune and susceptible plants, produced in crosses between immune and susceptible parents. However, their research work did not enable them to find morphological characters as the expression of immunity factors. So here we are again in the dark about the basis of resistancy.

For many years mildew has been a problem for Rose breeders. Amongst the mass of Rose varieties there is a regular disappearance of too susceptible strains. Although we know that a shining leaf is somewhat less susceptible than a non-shining one, the breeder is never entirely sure of his new form. The mildews have the peculiarity of attacking some of the strongest growers. The Crimson Ramblers had to surrender the field to the Wichuraianas, which lack the susceptibility of the ramblers. To-day many mildew-resistant climbers adorn our homes and gardens. We know that raisers will supply us with new and healthy varieties, but it is the task of the pathologist to find out why on so many Roses the mildew patches are restricted in growth and why the young autumn shoots are, so to say, eaten up by mildew. So it is with another fungous trouble, the black spot, Asteroma rosae. This fungus resembles the scab of our fruit trees, blackens the Rose leaves and causes an early loss of leaf. The Pernettiana Roses are notorious for their susceptibility to this disease.

These considerations will show that we need pathologists working along the borderland between pathology and genetics, and that we need pathologists with a gardener's eyes.

Latterly, pathologists have been largely occupied by another type of disease, namely the so-called mosaics, and the numbers of publications on the subject have been overwhelming. In addition to agricultural crops, like the Potato, some of the other vegetables have received large consideration. The chequering, crinkling, patching, curling, variegating, blistering and mottling of Tomatos and Cucumbers have been a subject of study. Without any doubt, the investigation of these symptoms will be "modern" for several years to come, as it is the unknown and indefinite causes of these plagues that fascinate the investigator—or is it fear that stimulates? Whatever will be our conclusions we know the diseases are infectious, and that several are carried from one plant to another by insects. Some investigators presume that protozoa are the originators, but it may be that a bacterium will prove to be the cause.

However troublesome these curl and mosaic diseases are to Cucumbers and Tomatos, it cannot be denied that the subjects are most dangerous to crops that are propagated vegetatively. The so-called deterioration of these plants is

* Abstracted from a paper on "The Relations Between Horticulture and Phyto-pathology," read by Prof. Johanna Westerdijk, Baarn, Holland, at the International Horticultural Congress, Amsterdam, Sept, 1923.

Digitized by Google

partly due to mosaics, *i.e.*, to a definite infectious disease.

The Raspberry mosaic disease (American Raspberry Yellows) seems more and more to find its way into Raspberry plantations. The variegating tops with the blistered leaves are to be seen from afar; the dwarfing of such shoots is evident, and the yield of fruit is small. The malady has not been subject to ample research, and the insect relations are not clear; but propagation by cuttings threatens a large dissemination of the disease.

Another mottling must be familiar to Dahlia growers. Mosaic is a trouble in several new varieties; the yellow patching of the leaves coincides with a stunted growth. I do not think the disease has seriously interfered with the breeding of new Dahlias, but it is there.

It has always been a marvel to me that our Apples and Pears have not been attacked by mosaic or related troubles. In the U.S. the Peach is suffering from an allied malady, which is called the "rosette." The destructiveness and danger of this disease on the other side of the Atlantic makes me draw your serious attention to this matter, as we are never sure that such a disease will not occur here. The Peach rosette, that was investigated by Erwin Smith, in 1881, was proved to be infectious. Smith transplanted diseased buds to healthy Peach trees. He also made a few experiments with Plum rosette, which behaved in the same way. We have in both these cases the common features of mosaic, the shortened internodal growth, together with the mottling of the leaves. McClintock did a great deal of research work, and transplanted the causal entity from one host to another. Buds of healthy Plums and Apricots were inserted on diseased Peach seedlings. The developing twigs, even after appearing clean for a year, showed rosettes and mottling. It is certain from these experiments that Plum and Peach rosette are identical. It has been possible to kill Plum and Peach trees within twelve months by inserting diseased buds into a susceptible host.

On the contrary it has been shown by different writers that the Marianna Plum is entirely immune. Some go so far as to indicate that the resistent stock exerted a marked influence on the virulence of the causal entity of rosette in the scion, which does not die out. The entity or virus cannot pass through the immune stock from one rosetted bud to another species inserted on the same stock. Almond and Cherry both are susceptible to rosette. Soil transmission does not seem to be of importance, but a sharp lookout for yellowing is advised to European gardeners.

And it seems to me that a mosaic is also a true qualification of the cause of the so-called "running-out" of Strawberries.

Much less known than the virus diseases is a malady called "reversion" or nettlehead, of the Black Currants, which possibly belongs to this group. As to its cause, one is absolutely in the dark. In England it has caused ravages, and in Holland it is called "bastardising." The bushes cease to bear normally, on account of the abnormal flowers. The leaves are reduced in form, in sub-main veins and marginal teeth.

The only control measures against these diseases consist in the careful selection of stock for propagation. We know that a Dahlia suffering from mosaic will retain the infection in its roots and give rise to new diseased plants. It should, however, be mentioned here, that Miss Wilbrink in Java has tried to purify "cuts" of sugarcane, suffering from "Sereh" disease, by hot-water treatment. These first trials have been a success. If investigations are carried along this line, they may become of great interest to horticulturists. Apart from this, every grower should be on the watch, and remove the worst infected plants.

We now consider a fourth congeries of diseases which requires serious investigation; the so-called physiological diseases, better called "inorganic." The first name is misleading, as every disease, be it parasitic or non-parasitic, is "physiological." Whatever be the name, these troubles require the help of a physiologist. Every pathologist should have "physiology" in his blood; without it he will not succeed. The parasitic diseases, on account of their epidemical character and their influence upon international commerce, have nearly entirely absorbed the labours of the pathologist. Moreover, a good gardener in many cases can cure or prevent these troubles himself. He knows often better than the man of science that the cause is a lack of manure, too heavy watering, drought or frost. But in other cases, the judgment of pathologists is needed. On behalf of fruit culture, I wish that pathologists would find the cause of "lithiasis" in Pears, and of "stipping" in Apples. An exact method for measuring hail injury is wanted. The gardener wishes to get rid of the various spots on his Orchid leaves did he only know how. This is a problem for the plant pathologist, who has to combine anatomical examination with physiological experiment.

GRASS ORCHARDS, OLD AND NEW.

THE beginning of grass orchards dates back to the early days of fruit culture in this country and long before Paradise stocks were discovered, and dwarf trees became more or less popular. The culture of Apples and Pears as standard trees in grass orchards was an institution in those counties which nature seems to have particularly adapted to this type of culture. Indeed, it may be said that orchards are part of our national history, so closely are they associated with the steady development of the country, its poetry and folklore. It was doubtless what he had seen in the orchards around Stratford, and the way trees were propagated in his time, that led Shakespeare to describe grafting as "the art which does mend nature."

Change it rather, for the art itself is nature, and it may be that the immortal bard saw, as one may see in many an orchard to-day, cases in which branches on trees have come into contact with each other, chafed and rubbed together for some time, until at length they have united and formed a natural graft—the art in fact which, as Shakespeare puts it, is nature. Many quaint legends are associated with Apple trees and orchards, in which witches hid and fairies danced, and childish though they seem in these days they belonged to an age of superstition and romance, and it seems a pity that they should be forgotten in the passage of time.

After all, there is something very charming in these old orchards, such as one finds them, in the Vale of Severn, for instance, where every farmstead has an orchard attached to it. These grass orchards are beautiful in the spring, when the grafted trees are masses of pink and white blossoms, and equally beautiful in the autumn, when the sun shines on the brilliantly red, striped and golden yellow Apples. There is neither law nor order about the typical old farm orchard; the trees seem to have been dropped in anywhere, with Mistleto growing on their limbs. Many of the trees are far too close together, some erect, others leaning this way and that, and others again with their stems flat on the ground, these trees having been blown over at some time, but with some of the roots still in the ground, and enough vitality in them to enable them to continue growing. If one looks carefully at the thick stems of many old Apple trees, and particularly Pear trees, one may observe a swelling which marks the point where the variety was grafted on the wild Crab or Pear stock, and grafted by the same methods as are employed to-day.

I venture this opinion, because last winter I rescued a log out of the stem of an old Apple tree that was being cut up for firewood, and there, in the middle of the stem, was the top of a stock about the circumference of a broom handle. Hundreds of years ago that stock was grafted by the notch system in the rind; one graft had grown and formed the tree which, in its long life, had doubtless produced many tons of fruit, but the other graft had died, and thus I found it, just as it had been put in after being hidden for years and years in the middle of the stem of the tree.

In some of the orchards there seem to be almost as many varieties as there are trees, and in view of the commercial requirements of to-day one wonders why the planters put in so many sorts.

It has to be remembered, however, that when these orchards were planted there was no commercial demand for Apples; the trees were planted to produce Apples to make cider, then the staple beverage in the western shires, and there were few nurseries in which fruit trees were propagated for sale. As a matter of fact, many of the local Apples in west country orchards that are known by quaint names, and known only in their particular districts, were raised in the first place from the seedlings which grew from the pips that were thrown out with the pomace from the cider mill, and while many of the Apples are of little value when judged by the standard of to-day, it has to be remembered that some of our best Apples originated in the same accidental way. The original object of the Apples and Pears was to make cider and perry, and if the tree cropped, this was the chief thing that mattered, but while in most of the old orchards vintage fruit may predominate, there are almost sure to be found a few others such as Blenheim Pippin, Ribston Pippin, Wyken Pippin or Ashmead's Kernel, the presence of which suggests that some farmer long ago had a taste for a good Apple, and took care to plant or graft a few varieties of the best quality then known for his own eating. Blenheim Pippin was a general favourite, and the vitality of this grand old Apple is amazing. In spite of all modern methods of cultivation, the best flavoured and most highly coloured fruits of Blenheim Pippin come from old orchard trees, and they come in quantity in a good season.

I am aware that there is a lot to be criticised in the old orchards, and some of them, according to modern views, might be taken as object lessons of how not to grow Apples. And yet they do grow, and grow in quantity, for whether it be for filling the cider casks or selling the fruit in the market, the revenue from the orchards compares favourably with that of any other branch of the farm. The value of an orchard is realised when one is put up for sale, even if it is old, or when the rent is being fixed for a farm with a big area of orcharding.

Hundreds of acres of new orchards have been planted in recent years, with standard trees raised in nurseries, and orchard planting in suitable districts has a lot to recommend it, because Apples as good as any that are produced under any other method of culture can be grown on standards in grass orchards, and what is all important they are grown at the least cost of production. There is no labour bill to be met for cultivation, the grazing pays the rent and a bit over, and when the trees come into bearing they continue increasing in profit for a generation to come. The varieties have been whittled down a good deal, but there are still too many, and growers continue to make the mistake of planting Apples like Lane's Prince Albert and Worcester Pearmain in grass orchards. I say this is a mistake, because the above Apples and others of similar habit fail to make big trees, which is the first requirement of an orchard standard. Bramley's Seedling, Newton Wonder, Blenheim Pippin, and Warner's King are the best type of Apple, and sufficient should be grown of each to count the crop in tons when the trees are in full bearing. In passing, I would mention a variety grown in the Severn Vale which is one of the best half-dozen Apples I know for orchard planting. In Hogg's *Fruit Manual* it is correctly described under the name of New Bess Pool, and one of the biggest Apple trees I have ever seen is of this variety, growing in a farm orchard at Kemerton, near Tewkesbury. The tree in question has a perfect habit, requiring very little pruning; moreover, it never flowers until June, and bears consistently every other season. The Apples are a convenient size for commercial purposes, even in colour, and in the best condition for market after Christmas. *G. H. Hollingworth.*

VEGETABLE GARDEN.

SOOT AS A CHEAP POTATO FERTILISER.

HAVING proved the value of soot in fruit houses, and especially in vineries, where I consider a three-bushel bag of soot costing 1s. 6d. is equal in manurial value to a 30s. bag of fertiliser, I resolved to try the effect of soot on Potatos on a piece of land of which my tenancy expired last September; this same land has been cropped with Potatos and Brassicas for the past thirty years.

As the ground became vacant it was ridged two feet four inches apart by spade. In April the soot was sown between the ridges, the Potatos set and the trenches filled in by the use of a hoe, thus minimising labour as much as possible. The experiment surpassed my greatest expectations. The growth of the Potatos was strong and of good colour; the haulm of Arran Comrade grew three feet high, and that of Kerr's Pink four feet tall. I have had the crop lifted, and from a hundredweight of each sort of seed have obtained the following results: Kerr's Pink, fourteen cwt.; Arran Comrade, thirteen cwt.; Dalhousie, thirteen cwt.; Eclipse, twelve cwt. Considering the dry season, a crop from twelve tons to fourteen tons per acre I consider very satisfactory. The tubers are a fine, clean sample, free from scab and disease. The land is of a slaty nature, and infested with a small black snail which in other seasons has made the tubers practically unsaleable. The soot was applied at the rate of six bushels to each hundredweight of seed, which was all Scotch grown. The cost of farmyard manure, 12s. per load, would be at least 24s. per hundredweight of seed, and its use entails much more labour. I have never had anything like these results from dung, and its cost, as compared with soot at 3s. per cwt. of seed tubers, is a consideration. Having secured the land for another year, I purpose planting the same varieties under similar conditions again, and shall anxiously await the results. *T. E. Furnell.*

THE CULTURE OF ASPARAGUS.

THE early part of November is a suitable time to prepare the site for a new Asparagus bed. This valuable vegetable succeeds best in a deep, sandy loam, but where the soil is not of this nature, it is necessary to prepare the ground specially to meet the requirements of the plant.

Trench the soil three spits deep in autumn, burying a thick layer of decayed cow or pig dung between each spit of mould. If the soil is of a light, sandy nature, raised beds are not required, but if the ground is heavy in texture and damp, with a clay subsoil, it will be necessary to trench the ground three spits deep, working in an abundance of fresh horse dung, plenty of old mortar, road grit, and decayed vegetable refuse. These materials will render the soil much more porous. An ample supply of decayed manure and leaf-mould should be well mixed in the top spit, and the surface left rough until the spring; on such ground it is beneficial to raise the bed slightly; the addition of the materials recommended will then ensure better drainage.

In March, beds three or five feet wide, with two-feet alleys between, should be formed. The alleys should be taken out a foot deep, and the excavated mould thrown on top of the bed.

Assuming the bed to be three feet wide, mark off two rows with a line, nine inches from each side of the bed, and put in sticks at fifteen inches apart along each line. If the bed is five feet wide, mark off a row down the centre, and one on either side of this, at a distance of eighteen inches.

Asparagus should be planted along ridges, where the rows are marked out along the bed; the tops of the ridges should be six inches above the proposed surface of the bed. Select a plant, place the base of its crown on the ridge, and spread the roots out on either side; let the ridge form a kind of saddle for the plant to rest on. Cover the roots at once with soil, as they are very sensitive to dryness, and should not be exposed longer to the air than is absolutely necessary. When all the plants are in position, add sufficient soil to raise the surface of the bed four inches above the crowns.

One-year-old crowns are the best for planting; if two or three-year-old crowns are used, they feel the check of transplanting very keenly. The best time to plant Asparagus is early April.

Under no circumstances should Asparagus shoots be cut until the fourth year after planting. It should be clearly recognised that the presence of large shoots is extremely essential to enable the plants to assimilate and manufacture the food for forming roots, and attaining the needful vigour to yield fine shoots.

For a light, sandy soil, the best natural manures are cow, pig, or moss litter dung; seaweed is also a first-class manure for such soils. For those of a heavy nature, horse dung, poultry manure, and decayed vegetable refuse are the best.

The most suitable concentrated fertilisers are guano, nitrate of soda, sulphate of ammonia, and sulphate of magnesia. Either of these may be applied at the rate of one ounce per square yard, in May, June and July. Salt may also be used liberally, say four ounces per square yard in April.

The best variety for early use is Connover's Colossal. Late Giant Purple Argenteuil is also a very fine sort. *W. Miller, Mill House, Horse and Groom Lane, Warley, Essex.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Eradication of Chickweed.—Perhaps some of your readers can give me advice as to a method of eradicating Chickweed. This weed is a perfect pest with me. During the dry period of this year I put in some intensive work cleaning, and had hopes that I had cleared it out. As soon as rains came, however, the growth appeared as thickly as ever. The wretched weed has not seeded here for the last three years. I dug it in and consoled myself that I was green-manuring my land, but, unfortunately, it is growing amongst bush Apple trees and Raspberries. I find a use for a limited quantity of it, for it is much relished by chickens kept intensively, but for this purpose I do not need so much of it. A good second to it is the Stinging Nettle. Seedlings of this weed come up in thousands in parts of the garden, although I have not tolerated seeding Nettles these three years. Still, I begin to wonder how long it takes to clear the ground of seeds. I certainly get more Nettles each year. A few years ago the owner of an estate near by tried to establish Nettles as a cover for game. The running stems of the plant were planted in quantity, but not one grew, which shows the perversity of Nature towards poor humans. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

Mr. B. Daydon Jackson.—I was pleased to see the portrait of my old friend in *The Gardeners' Chronicle* of October 27, with whom I was associated in botanical work during the last century. He is one of the most amiable men I ever had the pleasure of knowing, ever ready to help, while he was the mainstay of the Linnean Society's council, and many contributors, including myself, are largely indebted to him; there can be no question that the Linnean Society owes its present satisfactory condition to him He is a great worker, and conducts personally the correspondence of the Society with unfailing promptitude; he is justly proud of the distinction conferred upon him by the Scandinavian naturalists on the anniversary of the Society in London. I should like to write more, but, unfortunately, cannot. *W. Botting Hemsley, Broadstairs, Kent.*

Holland Park Hall Show.—Until the year 1916, I was a regular exhibitor of fruit at the Royal Horticultural Society's autumn fruit show, and I should like to point out to Mr. B. J. Mercer, Chart, Sutton, Kent, why the R.H.S. adopted the rule that if any exhibitor had a fruit plantation, apart from their private garden, and where fruit was grown for market, he was debarred from showing as a private grower. I believe it was the last show I exhibited at that an exhibitor entered in twelve classes, and, I believe, obtained eleven firsts and one second prize; he had 68 acres of fruit grown specially for market, besides trees in his private garden. I protested against his entry in one class, as I contended that no private grower could compete with a man who has 68 acres of fruit to gather from, and I myself had only 1½ acre. As I understand it, owners of private gardens from which surplus fruit is sold, are not debarred from showing; but those who have both private and commercial plantations are debarred. I was never dissatisfied with the judgment of the judges of fruit exhibits, but was often disgusted in the class for nine varieties of vegetables of the size and quality which cooks prefer in everyday cooking. I once had second prize pasted on my exhibit, and at the end had nothing at all, as I believe the chef considered my produce was not large enough! The times are not as they were before the war for gardeners, and that may have a good deal to do with the falling off of exhibits. The expenses are higher and many employers do not care for their gardeners to be spending much time in exhibiting. *A. Humphrey, The Bungalow, Bramshott, Liphook.*

The late Rev. H. J. Bidder.—May I supplement your splendid obituary notice on p. 270 with an account of the earlier associations of myself with the late reverend gentleman, whose versatility knew no bounds? When he was first appointed a fellow of St. John's College I was solo chorister there. I spent many weeks in the long vacation at his first vicariate's abode at the village of Fyfield, which was his first clerical appointment in the gift of the College, situated about eight miles from the city of Oxford. I believe he ranked music next to horticulture, for he was by no means amateurish in his manipulation of the organ and piano. He trained the village choir himself, and on all festive occasions solicited from his then president (Dr. Bellamy) the loan of two of the college boys to assist at his services, so that I became intimately acquainted with his personal charm and most varied gifts—indeed, he it was who persuaded me to engage in horticulture for a livelihood, by his recommendation of myself to the late Mr. Geo. Prince, the rosarian. At the tender age of ten years I was oft mystified at the then terrible botanical names he reeled off to me when parading the Fellows' garden at St. John's, adjacent to which, in the back quadrangle, his rooms were situated. The manner in which he would unpiece some floral specimen and explain its component parts was instructive, and helpful in many ways, in my later pursuits. His love of the river and boating was also very pronounced, whilst his attachment to the horse was a conspicuous part of his character. I was for many years the happy possessor of many letters of wise counsel from his pen; and I still possess a valuable present from him on my wedding day. Reverting to his love of music, I believe I am correct in stating that he alone was instrumental in securing Sir Walter Parratt, Bart., as his organist, when later Vicar of St. Giles', Oxford, at which time also Sir Walter was organist and choirmaster at Magdalen College. Dr. Wild, the present Bishop of Newcastle, succeeded him as Vicar of St. Giles', which Mr. Bidder had vacated to become bursar of St. John's College. His expositions from the pulpit were always scholarly. He was always brisk in his manner and speech, and keen to discern lapses in the younger generation, to whom he was not slow to administer advice in a kind but decisive tone. I very much doubt if it would be possible to find anyone more interesting in general conversation, or better addicted to ready wit of a kindly nature. As an old pupil I feel it an honour to add my tribute to the memory of a typical gentleman, scholar and guide. *Albert Upstone, Rotherham.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 1 AND 2.—The officers, committee and exhibitors of the National Chrysanthemum Society deserve heartiest congratulations on the unqualified success of the annual exhibition held at the Royal Horticultural Hall on the above dates. The hall was filled with fine displays from traders and amateurs, and it was no misfortune that the show was held at an early date, and that the season is a late one, because, while the exhibits were numerous, they were somewhat fewer than last year, and therefore there was more space for the proper display of the flowers. The Chrysanthemum specialists filled the whole of the space against the walls all round the hall, and these magnificent contributions made a grand setting for the competitive classes in the body of the hall. In the matter of quality the blooms were as fine and in some instances finer than ever seen previously at Westminster. The attendance was very large, and during the middle of the afternoon of each day the hall was inconveniently crowded. It must be remembered that all Fellows of the R.H.S. were admitted free, as well as members of the N.C.S.

The Floral Committee met at 11 a.m. on the first day and made several awards to novelties. Judging of new sorts and of the classes was completed in excellent time, and the doors were opened to the public ten minutes before the stated time of opening.

FIRST-CLASS CERTIFICATES.

Jean Pattison (II. 1.B.). A useful and attractive decorative variety, with sturdy, pointed florets that make up a firm flower suitable for market use. Colour, orange-bronze. (See Fig. 98.)

Aldyth (II. 1.B.). A handsome medium-sized flower of very attractive bright Chestnut-red colouring.

Felicia (II. 1.B.). A decorative variety of excellent form for floral arrangements and for market. Colour, a pleasing shade of pink.

The Wizard (II. 1.B.). This is a sport from Sorcerer, and, as in the case of the parent, the flowers are compact and travel well. Colour, pale Chestnut-red.

These four varieties were shown by Messrs. CRAGG, HARRISON AND CRAGG, who obtained four First-class Certificates and showed only five varieties.

Gloriosa (II. 1.B.). In this shapely and attractive variety the blooms are a pleasing shade of golden-bronze.

Gigantic (II. 1.A.). A large variety of exhibition style, with broad, curling and loosely incurving florets of silvery-pink colouring.

These two varieties were shown by Mr. H. SHOESMITH.

Progress (I. A.). It is not often a new incurved variety is shown, but this one was welcomed as it has good form and the colour is soft silvery-mauve. Shown by Mr. H. THORPE, Worthing.

Mrs. E. W. Catlow (V. 1.A.). A large-flowered single variety, with broad, rich yellow florets. Shown by the BRIDGEWATER NURSERIES, LTD.

Flame (V. 1.A.). A glorious single variety, elegant and large, the petals slightly pointed. The colour is rich Chestnut-crimson, with yellow zone round the deeper yellow eye. Shown by Mr. P. LADDS.

Mrs. A. B. Hudd (V. 1.A.). Another very fine large-flowered single variety, with broad florets of very rich golden-yellow colouring. Shown by Mr. G. CARPENTER, West Hall Gardens, Byfleet.

Norman Davis (II. 1.A.). An attractive large-flowered Japanese variety, with long, broad, drooping florets of deep crimson colouring, with old gold reverse, which is shown on the slightly unturned tips of some of the florets. Shown by Mr WALTER JINKS, Thames Ditton.

Mrs. W. Seymour (II. 1.A.). A large exhibition Japanese variety, with loosely curling florets; colour, soft lemon-yellow. Shown by Mr. BAXTER, Lockerly Hall Gardens, Romsey.

Dorothea Edwards (II. 1.B.). A medium-sized Japanese variety of decorative style. The colour is a pleasing shade of pearly-pink.

Framfield Orange (II. 1.B.). A very beautiful decorative Japanese variety of useful size and good form; colour, golden amber, tinted orange. These two varieties were shown by Mr. NORMAN DAVIS.

COMPETITIVE CLASSES.

There were twenty classes for cut blooms open to competition amongst all amateurs, and in nearly the whole the general quality of the Japanese blooms in six varieties of stipulated colours. Here the first prize was won by the DOWAGER LADY ANNALY (gr. Mr. D. Cameron), Holderby Hall, Northampton, with a superb collection, which included in the vase of Majestic the finest blooms in the whole show. The specimens of Mrs. George Monro, Princess Mary, Mrs. G. Gibson and Victory were also of great merit. The second prize was won by the LORD WANDSWORTH COLLEGE (gr. Mr. E. H. Pearce), Long Sutton, with a very meritorious collection of such sorts as Sir E. Letchworth, Majestic and Mrs. George Monro.

FIG. 102.—A VASE OF LARGE-FLOWERED CHRYSANTHEMUMS (MAJESTIC) IN THE FIRST PRIZE "HALL DECORATION" EXHIBIT AT THE NATIONAL CHRYSANTHEMUM SOCIETY'S SHOW, NOVEMBER 1 AND 2.

blooms was very high. This was particularly so in the larger classes. The William Wells' Memorial Class required thirty-six Japanese blooms in twelve varieties, three blooms of each, and as these were set up in vases placed on low tabling they made a splendid effect. The first prize was won by Capt. R. B. BRASSEY (gr. Mr. J. G. Quinn), Cottesbrooke Hall, Northampton, with blooms of the largest size and of high quality. The very best were Rosemary Simmonds, Majestic, Mrs. George Monro, His Majesty and Princess Mary. The second prize was awarded to E. A. MOCATTA, Esq. (gr. Mr. W. Holden), Addlestone, for a very good collection, which included almost perfect blooms of Majestic, Peace, Mrs. R. C. Pulling and Mrs. George Monro.

Good as were the blooms in the previous class, they were even better in that for eighteen

The Holmes' Memorial Challenge Cup class retains all its popularity with exhibitors and the public alike, and the collections of thirty-six distinct Japanese blooms illustrated a high standard of cultivation. In nearly every instance the blooms were decidedly too large for the regulation show boards, so that the outer florets overlapped. But, although the blooms were of immense size, they were also of first-rate quality. The cup and first prize were won by E. A. MOCATTA, Esq., with a magnificent collection. His very best sorts were A. F. Tofield, Wm. Rigby, Mrs. P. Murray, Mrs. G. F. Shawyer, Majestic, Ryecroft Triumph, Princess Mary, Mrs. D. Andrews, Peace and Shirley Golden. The LORD WANDSWORTH COLLEGE, which was second, included especially good blooms of Peace, Shirley Golden, Mrs. George Monro, Renown, Rose Day and Thorpe Beauty; 3rd, Col. THOM-

Digitized by Google

son (gr. Mr. D. Barnard), The Manor House, Effingham.

MAJOR DALGETY (gr. Mr. W. Baxter), Lockerly Hall, Romsey, proved to be the winner of the President's Silver Trophy with twenty-four well-finished blooms. Mrs. George Monro, F. Spring Watts, Majestic and Mrs. R. C. Pulling were the very best. Major DALGETY also won first prize in the class for twelve Japanese blooms, but these contained too many white and yellow varieties (there were four of each) to be an ideal collection, though the quality was very high. The second prize collection of ALICK MEDEN, Esq. (gr. Mr. G. Pound), North Hall, Cuckfield, also lacked colour. In this class LADY ANNALY showed the most perfect bloom of Mrs. George Monro in the show. Major DALGETY continued his successes by also winning first prize with six excellent Japanese blooms of such sorts as Lady Talbot, F. Spring Watts, Caroline Soer and Majestic. W. H. ALLEN, Esq. (gr. M. H. Blakeway), Bromham House, Bedford, was second.

Incurved blooms, shown on boards, were only of moderate quality, and not nearly equal in merit to the first prize specimens of last year. The best twelve were shown by H. T. KERR, Esq. (gr. Mr. J. J. Horne), The Moat, Ascot, and his best were Buttercup, Romance, Clara Wells, C. H. Curtis, and Emblem Poitevine.

The EXORS. OF THE LATE MARQUESS OF RIPON (gr. Mr. T. Smith), Coombe Court, Kingston, were first with six vases of Decorative Chrysanthemums, for Anemone varieties, and for a vase of small-flowered singles. Mr. J. H. HUSSEY, Malford Lodge, Exeter, had the best Pompons, both disbudded and naturally grown. The first prize for nine vases of large singles, shown by Mr. CHALMERS, included especially good blooms of Supreme, Mavis, Susan and W. Wingfield. This was a very good class, and the second prize collection by F. J. YARROW, Esq. (gr. Mr. A. Robertson), St. John's Wood, was also of great merit. His vases of Crimson Velvet, Mrs. W. Smith and Reginald Godfrey were excellent. Mr. CHALMERS was also first with six splendid vases of large singles.

The George Monro Cup competition was open to all members, trade and amateur, and this year it was won by F. J. YARROW, Esq., with twelve particularly good vases of large Singles. As in the other class, his vases of Crimson Velvet were greatly admired, while Phyllis Cooper, Mrs. W. Smith, Molly Godfrey and Lizzie Roberts on were also of superb quality. In the same section the EXORS. OF THE LATE MARQUESS OF RIPON were first with six vases of very pretty Anemone Singles: Thora, Ceres and Cordelia were very charming. ALICK MEDEN, Esq., won the first prize with three excellent vases of Large Singles.

The amateurs' exhibits in section six were of gratifying quality and, for the most part, the competition was very good. The chief first prize winners were Mr. R. BARBER, Mr. J. H. GODDARD, Mr. J. H. HUSSEY, Mr. R. J. JOLLIFFE and Mr. J. B. PROCTOR.

FLORAL DECORATIONS.

When viewed as a whole the various classes for decorative display were particularly successful, and there were some charming arrangements. The first prize vase of Single Chrysanthemums, arranged by F. J. YARROW, Esq., was very imposing, though arranged with a trifle too much formality. The EXORS. OF THE LATE MARQUESS OF RIPON were second, and were awarded the first prize for a highly decorative vase of large incurved blooms. F. J. YARROW won first prize with an imposing vase of magnificent large Japanese blooms. In the class for a basket of Chrysanthemums Mrs. ROBINSON was placed first with a basket of very large size, while the EXORS. OF THE LATE MARQUESS OF RIPON were second with a pleasantly restrained arrangement.

The new class for "An Arrangement of Chrysanthemum Blooms, suitable for a Hall Table, or Sideboard Decoration," resulted in a good competition, but it did not bring any arrangement of outstanding value. G. RICHARDSON, Esq., was first for a large ornamental jar of excellent blooms of Majestic (see Fig. 102), but the accompanying small show jars of blooms were entirely out of harmony. Mrs. ROBINSON was awarded second prize for a large, spreading arrangement in which grasses and foliage predominated. With beautiful blooms of Dawn of Day, R. BARBER, Esq., won first prize in the class for a vase of five blooms of any Japanese variety. G. RICHARDSON, Esq., had the best large vase of Chrysanthemums and the best bowl of Singles, while C. E. THOMPSON, Esq., Forest Hill, was first with a well-arranged vase of large Single varieties.

The Affiliated Societies class resulted in very good competition, and the representative collections were of considerable merit. The trophy and first prize were won by the SUTTON, KINGSTON, THE DITTONS AND DISTRICT SOCIETY; 2nd, EASTBOURNE HORTICULTURAL SOCIETY; 3rd, BERKHAMSTED HORTICULTURAL SOCIETY.

TRADE GROUPS.

Practically all the large trade growers supported the show with extensive collections of well-grown blooms, which were arranged on a wall space around the hall.

Mr. H. J. JONES had a very imposing group composed of tall stands of the best exhibition varieties against the wall, and lower arrangements, chiefly of decorative sorts, in front. An enormous number of excellent blooms were arranged with great skill. The principal exhibition Japanese varieties were Rose Day, Mrs. R. C. Pulling, Princess of Wales, Mrs. Gilbert Drabble, Majestic, Mona Davis, Mrs. George Monro and Wm. Rigby. His Singles included Mrs. A. B. Hudd, Absolute and Golden Marvel (Large Gold Medal and the Clay Medal for the best trade display).

A particularly attractive collection was set up by Messrs. K. LUXFORD AND CO., and in this tastefully arranged group the principal Japanese sorts were Poulton's Climax, Princess Mary, Majestic, Rose Day, Harry Clements, F. Spring Watts and Mrs. John Balmer. These useful market-sized varieties included Raffinesque, gold-tipped pink, and Sorcerer, orange-bronze, while amongst the excellent Singles there were Alberta, Barbara, Mrs. W. J. Godfrey, Phyllis Bryant and Mrs. Thos. Hancock (Gold Medal).

The large group arranged by Messrs. W. WELLS AND CO. included many splendid blooms, and their beauty was enhanced by the association of brilliantly-coloured sprays of Scarlet Oak. Amongst the many valuable Japanese sorts, Viscount Chinda, Mrs. George Monro, Mrs. Gilbert Drabble, Mrs. B. Carpenter and Wm. Rigby were very prominent. The Anemone varieties Mabel Weston and Aphrodite were particularly graceful (Small Gold Medal).

Near the gallery Messrs. CRAGG, HARRISON AND CRAGG had an excellent collection of market varieties, which would also be of great value in the private garden. They included J. H. Blythe, a well-formed Single with a narrow golden zone and of crimson-red colour with a rosy sheen; Jean Pattison (see awards), Enid Elder, deep yellow; Felix, a rosy amaranth Japanese, and Elspeth, a very decorative satiny-mauve Anemone flowered variety in spray form (Silver-Gilt Medal).

Mr NORMAN DAVIS had a smaller collection, which included Framfield Orange: Madame H. Foreau, of rich purple colour: Norman Fairs, Mrs. Fred Fairs, several valuable seedlings, and In Memoriam, a splendid Japanese variety of Mrs. George Monro type, but brighter in colouring (Silver-Gilt Medal).

Singles predominated in a collection set up by Messrs. W. J. GODFREY AND SON, and in addition to a large number of good cut blooms, they had excellent plants of Exmouth Sunset, stippled with red, Exmouth Glory and October Gold, growing not more than eighteen inches high in six-inch pots and particularly well flowered (Large Silver Medal).

A pleasantly arranged collection from Mr. H. WOOLMAN included Oda, Viscount Chinda, Mrs. George Monro and Rose Day, of the large Japanese type, and Mary Richardson, Bertha Fairs and Jessica, of the Singles (Silver-Gilt Medal). Mr. Wm. YANDELL set up an attractive group of small decorative varieties. The massed vases of Red Almirante, Cranford Yellow Hesperus, Harvester, Uxbridge Pink and Cranfordia were very successful (Large Silver Medal).

Such excellent Singles as Absolute, Mrs. R. H. Harris and Mrs. Thos. Hancock with the market Japanese varieties Mrs. Rupert Wilks, Miss Verona Chichester and Hon. Mrs. Dalgetty were well arranged by Messrs. J. W. COLE AND SON (Silver-Gilt Medal). Mr. L. MILLS had a corner group of very floriferous dwarf pot plants (Silver-Gilt Medal), and Messrs. CARLTON WHITE exhibited a pleasing table decoration of Chrysanthemums.

NATIONAL SWEET PEA.

ABOUT fifty members of the National Sweet Pea Society were present at the annual general meeting held at the Royal Horticultural Hall early in the afternoon of Tuesday, October 30. Mr. Robert Bolton presided.

The Annual Report of the Committee for the year 1922-23 was presented and showed that the Society had had a very successful floricultural year notwithstanding climatic difficulties. Special and kindly reference was made to the Bath exhibition and to the very able assistance given to the Society by the Mayor and Mayoress and the Corporation of that city. It appears there has been a slight increase of membership, but chiefly owing to the fact that the expenditure on the Society's trials both for 1922 and 1923 came into the present year's accounts, there was a deficit of £83 on the year's working, the total turnover for the year being £531 8s. 2d. The Society has, however, £100 invested, besides numerous stands and other show properties. The Trustees of the Henry Eckford Memorial Fund notified the award of the Henry Eckford Medal to Mr. Charles H. Curtis.

The report and accounts, as presented, were adopted by the meeting.

Mr. J. S. Brunton was elected President for the ensuing year, and Mr. Robert Bolton was thanked for services rendered as President during the year just ended. It was with regret that the members learnt that Mr. Edward Sherwood desired to be relieved of the duties of Hon. Treasurer, owing to pressure of business, but they were pleased to learn that Mr. J. M. Bridgeford was willing to undertake the duties of that office. Mr. Bridgeford was unanimously elected. The eligible retiring members of Committee were re-elected, and Messrs. R. Bolton, C. H. Curtis, F. Wheler, W. Dixon, C. Unwin, R. Ascroft, and W. Coates were appointed to fill vacancies arising. Mr. T. Jones and Mr. B. Peyman were appointed corresponding members of Committee. Mr. A. C. Bartlett was unanimously re-appointed Secretary; Mr. England, Syon House, Brentford, appointed Trials Superintendent for the ensuing year, and Mr. J. S. Brunton re-appointed Editor of the Society's *Annual*. In this latter connection an amateur member present asked that more practical advice should be given in the *Annual* to amateur cultivators. This matter was referred to the Publications Committee to deal with.

The meeting then proceeded to elect the Floral Committee for 1924. There were twenty-one nominations for nine positions; the members receiving the largest number of votes in the ballot were Mr. Robert Bolton, Mr. A. Ireland, Mr. C. H. Curtis, Mr. C. Unwin, Mr. T. Stevenson, Mr. J. Stevenson, Mr. H. D. Tigwell, and Mr. Donald Allen. Three members tied for ninth place, and in the second ballot Mr. T. Jones was successful.

Thanks were accorded the officers and Committee for services rendered during the year, and a special vote of thanks accorded Mr. R. Bolton for his generous support of the Society and for presiding at the meeting.

READING AND DISTRICT GARDENERS'.

THE fortnightly meeting of this Association was held on Monday, October 22, when the president, Mr. Councillor Frank E. Moring, presided over a large attendance of the members. The lecturer for the evening was Mr. W. Auton, gardener to the Rt. Hon. Viscount Elveden,

Digitized by Google

Pryford Court, near Woking, and his subject was "A Substitute for Farmyard Manure." The keenest interest was manifested in his discourse, and this was shown by the animated discussion which followed the lecture.

In the competitions for a collection of vegetables (four sections) there were seventeen entries, which made a splendid show, the finest seen in Reading for many years. The awards were as follow :—

Open to all, six distinct kinds (seven entries) : 1st, Mr. J. Wynn, Hammonds Gardens, Checkendon; 2nd, Mr. D. Turner, Coley Park Gardens, Reading; 3rd, Mr. A. W. Gower, Calcot Grange Gardens, Calcot. Members not employing more than one assistant : 1st, Mr. H. Goodyer, Stonham House Gardens, Calcot; 2nd, Mr. H. Goodchild; 3rd, Mr. H. Day, Westwood House Gardens, Tilehurst. Single-handed Gardeners : 1st, Mr F. Haines; 2nd Mr. H. Reeves, Broadfield House Gardens, Reading. Amateurs and Allotment Holders : 1st, Mr. A. E. Kirby, Reading; 2nd, Mr. R. Buller, Reading.

In the non-competitive section a First-class Certificate was awarded to Mr. C. J. Howlett, The Yews, Earley, for Figs in pots and Red Currants; and to Mr. W. Sharpe, Sidmouth Grange Gardens, Reading, for excellent specimens of Tender and True Parsnips. Other exhibits staged were Violets, by Mr. G. Tovey, Leighton Park Gardens; eight vases of Antirrhinums, by Mr. A. H. Fulker, The Gardens, Elmhurst, Reading; Capsicums by Mr. G. Wheeler, Reading, and a dish of Potatos grown from tubers planted in July, by Mr. E. Iles, Reading.

THE fortnightly meeting of this Association was held on Monday, the 5th inst. Mr. A. H. Fulker presided. A large number of members were present.

The subject for the evening was "Herbaceous Plants and Borders," and was introduced by Mr. W. Wiseman, Hare Hatch, Twyford. He stated that he wished to bring before their mind's eye the garden pictures of thirty years ago, with intricate bedding schemes, seldom varying in character, and contrast them with the ever changing pictures made by the best borders of to-day. Mr. Wiseman said that the planning and planting of herbaceous borders have by no means reached the bounds of possibility. Explorers are continually discovering new plants with which to enrich our gardens, while nature's wealth of colour and form is being always added to by hybridisation and selection. The lecturer then dealt with the practical side of the question, the shape of borders, paths, plants to use, grouping of plants, size and form of groups, and use of coloured foliage plants. An excellent and instructive discussion followed the lecturer's remarks. In the competition for three vases of decorative Chrysanthemums, there were no fewer than ten entries, and many choice blooms were staged. The awards were as follow : First, Mr. A. W. GOWER, Calcot Grange Gardens; second, Mr. A. H. FULKER, Elmhurst Gardens, Reading; third, Mr. F. J. GREEN, Aldermaston Court Gardens. In the non-competitive section, a First-Class Certificate was awarded to Mr. A. W. GOWER for excellent plants of Chrysanthemum Blanche Poitevene about eighteen inches high, and carrying nine or ten well formed blooms, also plants of Chrysanthemum W. Turner. A similar award was given to Mr. H. WYNN, Quern's House Gardens, Goring Heath, for excellent buttons of two varieties of Brussels Sprouts. Other exhibits were Cypripedium Spicerianum, by Mr G. WHEELER, Southcote Road, Reading, and finely berried sprays of Barberries by Mr. C. TERRY, Earley.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

SIR WILLIAM LAWRENCE, BT., presided at the annual dinner of the United Horticultural Benefit and Provident Society, held on November 1, at the Imperial Hotel, Russell Square, W.C. The attendance, including Lady Lawrence and many other ladies, numbered nearly one hundred, the members present being mostly those resident in the metropolitan district. The gathering was one of the most successful the Society has held for many years, and Sir William proved an able and humorous chairman. After the usual Royal toasts had been honoured, the chairman proposed continued success to the United Horticultural Benefit and Provident Society, and in so doing said he could not help but regret that the Society had such a large title. He had gone very carefully into the working of the Society, and was very gratified to find that it was rendering such a large amount of assistance to its members, and was being worked in the most economic manner possible. He was glad also to find that not one, but all classes of horticulturists were included in the Society's membership, and to a very large extent also in the managing body of the Society. Although not eligible for ordinary membership himself, he hoped to have the pleasure of being an honorary member, and promised that during his visits to the gardens of friends, he would do his best to interest employers in the work of the Society, so that they might place the advantages of membership before the members of their garden staff.

Mr. C. H. Curtis, Chairman of Committee, responded to the toast, and after thanking Sir William for his promise to act as a missionary on behalf of the Society, pointed out how invaluable the Society had been to gardeners. He stated that during its existence the Society had paid no less than £14,500 in sick benefits. The sum of £3,217 had been expended by the society in alleviating special distress, whilst the nominees of deceased members had received a total of £5,892. One member had received no less than £480 since he had been a member, and there was still £10 in his deposit account. There were several members who had received £300 in sick and distress pay during their membership, and quite a few who had received £100 each. Mr. Curtis further stated that the State Section had dispersed £3,355 in sick pay, and there had been no fewer than three hundred and thirty-five maternity claims on that section. The State section was managed so admirably that there was the considerable balance of £1,600 in hand, and it was proposed to utilise this over a period of five years, to help members who require dental treatment, surgical treatment, nursing, etc. The invested capital of the Society amounted at the end of last year to £65,686, and since then over £1,000 had been added, thus making a total of nearly £67,000 invested in good trustee stocks. Mr. E. F. Hawes proposed the toast of "The Visitors," to which Mr. A. Dawkins very ably responded, combining humour with practical advice, and suggesting that if the Annual Report was shortened, and the clear facts only mentioned, it would probably be read more. Mr. T. Slade, of Messrs. Protheroe and Morris, also responded to the toast of the visitors in his usual able manner, and referred to the extraordinary good management of the Society, which was much more practical than ordinary insurances. "The health of the Chairman" was proposed by Mr. Butler, Vice-Chairman of Committee, and was accorded musical honours. An excellent programme of music was provided throughout the evening, the artistes being Mrs. C. Lumley, Capt. C. Chatt, Mr. Frank Gale, Mr. Frank Jacobs, Mr. Fred Verity and Mr. W. Willmott.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

OCTOBER 18.—*Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. Birchenall, A. Burns, A. Coningsby, J. Cypher, J. Evans, J. Howe, W. Morton Jackson, A. Keeling, D. McLeod, E. W. Thompson, and H. Arthur (Secretary).

FIRST CLASS CERTIFICATES.

Cattleya Mrs. Gratrix (*Lady Veitch* × *intertexta Juliettiae*). A pure white flower of good form and texture, with a deep yellow throat. From S. GRATRIX, Esq.

Odontoglossum crispum var. Orestes. A full round flower, with a deep blotch of colour on the large, flat lip. From P. SMITH, Esq.

AWARDS OF MERIT.

Cattleya Venus Orchidhurst var. and *Laelio-Cattleya Appam var. Golden Crown* (*C. Dowiana* × *L.-C. Scylla*). From S. GRATRIX, Esq.

Odontioda Helma (*parentage unknown*). From P. SMITH, Esq.

GROUPS.

S. GRATRIX, Esq., West Point (gr. Mr. J. Evans) staged a group for which a large Silver-Gilt Medal was awarded.

Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns) were awarded a Silver-Gilt Medal for a group.

Messrs. J. CYPHER AND SONS, Cheltenham, staged a group in variety and were awarded a Silver Medal.

PORTSMOUTH HORTICULTURAL.

THE 32nd annual exhibition of Chrysanthemums, fruit and vegetables, arranged under the auspices of the Portsmouth Horticultural Society, was opened at the Town Hall, Portsmouth, by the Mayor, Alderman F. G. Foster, J.P., on Wednesday, the 31st ult., and continued for the two following days.

The total entries were not quite so numerous as last year, but the general quality of the exhibits was splendid. Considering the lateness of the season, and the adverse climatic conditions, the Chrysanthemums were exceptionally fine. The challenge cup offered for three dozen Japanese blooms of 18 varieties was won by Mr. J. LOVE, of Cowes, with a very fine collection. The exhibits of six single Chrysanthemums displayed in vases containing half a dozen blooms each were exceedingly attractive. The group of Chrysanthemums, in pots, arranged for quality and effect, covering a space of 60 square feet, with which Mr. W. B. JEFFREYS, of Clarence Parade, Southsea, won the challenge cup in that particular class, was a remarkable exhibit. Mr. JEFFREYS also secured the challenge cup offered for six pots of Chrysanthemums. This exhibit was not quite so good as last year, but at the same time was very creditable. The group of single Chrysanthemums arranged in pots for quality and effect in a space of 50 square feet made a very notable contribution to the show. The exhibits of one vase of 12 large single disbudded blooms was another fine feature. Mr. E. J. MEREDITH, of Osborne Road, Southsea, won the silver challenge cup for a group of Chrysanthemums in pots, in a class restricted to amateurs. This is the second year Mr. Meredith has achieved this success. He was closely followed by Mr. S. W. Wickens only a few points behind, which is all the more creditable in view of the fact that this was Mr. Wickens' first exhibit. The six sprays of single Chrysanthemums was another splendid class, and cut Japanese blooms were also well exhibited. The exhibits in the class for a vase of single Chrysanthemums were of outstanding merit.

The vegetables were the finest exhibited in the town for a number of years. The collections of fruit, although below the usual standard, were of excellent quality considering the bad season.

The opening ceremony, which was presided over by Councillor W. E. Gill, chairman, was attended by a large number of people. In calling upon the Mayor to open the exhibition the chairman explained that the object of the Society was the encouragement of the cultivation of flowers and vegetables. The exhibits were not quite so numerous in the fruit classes owing to the bad season, but the vegetables were up to the usual standard, while the flowers were in some cases considerably better. Nearly all the exhibits were grown by amateurs and working people inside the town, very few being grown outside. People who were interested in that sort of thing were always good citizens.

The Mayor congratulated the Society upon the excellent show.

Obituary.

William Robertson Begg.—We regret to record the death at his home, Nursery Cottage, Burnside Nurseries, Aberdeen, on Wednesday, 31st ult., of Mr. William Robertson Begg, for many years a conspicuous figure in Scottish nursery circles. Born in 1833, deceased had attained the ripe old age of 90 years, during which period he enjoyed capital health up till quite recently, when a sudden illness proved too severe for the nonagenarian. Mr. Begg started his life work as an apprentice gardener at Woodhill House, Aberdeen, situated within half a mile of the house where he spent the evening of his days. Thirsting for more knowledge of his craft, he served successively as gardener at Cullen House, Fasque, Belhelvie Lodge, and Knockando House. About 45 years ago a manager was wanted for the nurseries at Burnside and Silverhillock, and the exceptionally fine qualifications Mr. Begg was able to submit secured him the post. The nurseries then were the property of Messrs. Cardno and Darling, but when that firm retired they were acquired by Messrs. W. Smith and Son, Ltd., Aberdeen, who still retain them. Mr. Begg was for nearly 40 years a partner in the firm. Mr. Begg had a remarkably successful career as a nurseryman, and during his long tenure of office superintended the planting and raising of more forest trees than any other nurseryman in Scotland. His wide experience in, and fine knowledge of, gardening and forestry made his counsel in great demand over a wide sphere, while landed proprietors from all quarters sought his advice in connection with the laying out of their estates. Although in semi-retirement for a number of years, Mr. Begg continued to take a warm and keen interest in all matters pertaining to his life's work. He was predeceased by his wife many years ago, and is survived by four of his family, all of whom occupy important positions. One son is in his father's firm.

James Harris.—We regret to learn of the death of Mr. James Harris, of Blackpill Nurseries, Swansea, which occurred on Saturday, October 27. Mr. Harris was seventy-eight years of age, and for over half a century has been one of the most prominent horticulturists in the west of England and South Wales. He was formerly head gardener to Mrs. J. H. Vivian, at Park Wern, and later gardener to Lord Swansea, at Singleton Abbey, a position he occupied for about twenty-one years. After relinquishing private service he took up the commercial side of horticulture, and managed the Blackpill Nurseries with great success. Among his most noteworthy achievements was the introduction of Sir John Llewelyn Potato. He leaves two married daughters and a son, who will continue to manage the nursery business at Blackpill.

TRADE NOTE.

Smaller supplies of Potatos are being marketed and, with trade showing a further slight improvement at several centres, recent quotations are generally maintained, while at London most varieties record an advance of about 5s. per ton on the week. At Liverpool nearly all descriptions of Potatos are from 5s. to 10s. per ton dearer, and at Manchester, several late varieties have advanced 10s. per ton. Trade continues quiet at Wisbech, but best white varieties are in better demand and have a firmer tendency. Imports of Potatos registered during the week ended October 27 amounted to 102 tons, of which 58 tons came from Holland. For the weeks ending October 6, 13 and 20, total imports amounted to 1,213, 146, and 178 tons respectively.

THE WEATHER.

THE WEATHER IN SCOTLAND.

October was, on the whole, comparatively mild, ground frost being only registered on one day, viz., the 14th. The highest maximum temperature of 61° occurred on the 1st, this being a continuation of the exceptional warmth of the last days of September. The lowest maximum of 49° was on the 23rd, the mean maximum for the month being 54°, which is just about normal for the district. The highest minimum of 48° also fell on the 1st, with the lowest of 34° on the 14th and a mean of 42° giving a range of 12°. The minimum was 2° above normal. Bright sunshine was registered to the extent of 109.1 hours, giving an average of 3.53 hours for each day and a percentage of 34, which is above the normal for October. Although rain days were frequent, the total of 2.01 inches was well below normal. The wettest day was the 26th, which yielded 0.58 of an inch. On nine days there was no precipitation. The temperature of the ground at 1 foot deep fell gradually from 54° at the beginning to 46° at the close. Moderately high winds, chiefly from the south-west, were frequent, with a severe gale on the 9th, doing structural damage. Barometric pressure was variable, the highest reading of 30.19 inches on the 4th and the lowest 28.51 inches on the 27th, the end of a week of low pressure. Rainbows were observed on the 9th and 31st at 4.3 p.m. and 9 a.m. respectively. The sky was often hazy, but there were no dense fogs. *John Davidson, Director of Studies, Training College Gardens, Mayfield, Dundee.* November 7, 1923

ANSWERS TO CORRESPONDENTS.

Cinders and Coal Ash in Soil: *R. M. P.* We can advise no method of removing cinders and coal ahes from your soil other than by the use of a sieve, but, if the area is of considerable extent, this would involve much labour. As, however, you state that the soil is very light, it might be possible to remove a considerable portion of the cinders in this way when the ground is very dry. Beyond any effect sulphur present in the ash might have, we do not think the materials will have any injurious effect on plants, although they may spoil the texture of the soil and render it too porous. If the soil is trenched to a considerable depth and the ashes placed in the bottom, they would not be in evidence.

Clematis, Early and Late Flowering: *P. P.* Clematis, Lady Northcliffe, deep lavender; alba Magna, pure white; Nellie Moser, light Mauve; Madame Edward André, velvety red, all flower from July to October; The Queen, lavender, flowers in May and June.

Correction.—A correspondent draws our attention to an error in our report of the last R.H.S. meeting. He states that the exhibit of winter-flowering Begonias was shown by Mrs. Sofer Whitburn, and not Mrs. Sofer Wilburn, as given in the report.

Exterminating "Cat-Tail": *S. A. E.* The plant you send is Equisetum or the Horsetail weed, which indicates a wet or damp and sour soil. If your land is wet you should drain it by putting down a line of small pipes on each side of the site, and at a depth of three feet. Then dress the ground with 4 to 6 ounces of quicklime to the square yard, and work it in by forking or hoeing. The next best way to exterminate the weed is to cut the stems below the surface with an old knife early in the season, and repeat this as often as the shoots appear on the surface. These young shoots are produced at the expense of food stored up in the underground rhizomes during the previous year, and the more often they are cut the more rapidly the plants will become exhausted and cease to appear. If the ground were trenched three feet deep and all the rhizomes and roots that can be seen were taken out, the trouble would be very largely reduced by the one operation. The first two operations above described should be carried out this season. The draining and liming will make the ground unsuitable for the weed; but if spores get carried on to the ground from wild Equisetums, and seedlings appear, cut them repeatedly below the surface, and they will soon cease to grow.

Grapes and Figs with Brown Markings: *W. L.* The brown markings on the Grapes are due to mechanical injury brought about probably by rubbing the berries when the bunches were being thinned. This may have occurred through the bunches coming in contact with the head of the operator. Send a specimen of the Fig in a more advanced state of the affection.

Grubs Attacking Cyclamen: *H. S. L.* and *J. H. C.* The grubs sent by *H. S. L.* had escaped from the box. We suspect that they are weevils, sent also by *J. H. C.*, and these should be trapped with pieces of Potato or other vegetable. Examine the traps at night, as weevils feed principally in the dark.

Lopping Plane trees. *J. W., London.*—Plane trees may be lopped severely without any danger of materially injuring them, and the lopping may be done at any time during the winter. After having been lopped the trees will make a number of twiggy shoots around the end of the cut branches. If let to grow these will become very congested and present a poor effect, so that it would be wise to thin them, but it is not advisable to cut them lopping has been done. Ash trees may also be lopped without any harm accruing to them, but it is not advisable to cut them quite so severely as may be done with Planes, though they may be shortened to near the bases of the secondary branches.

Names of Fruits: *J. S.* 1, Manx Codlin; 2, Adam's Pearmain; 3 and 5, not recognised; 4, King of the Pippins; 6, Ribston Pippin; 7, Emperor Alexander; 8, Cox's Pomona; 9, Duchess's Favourite; 10, Fearn's Pippin; 11, Pear Beurré Diel.—*J. A.* Green Apple, Waltham Abbey Seedling; red, Cellini.—*F. A. A.* 1, Beauty of Kent; 2, St. Sauveur; 3, D'arcy Spice; 4, Wyken Pippin; 5, White Nonpareil; 6, decayed; 7, Alfriston; 8, Gloria Mundi; 9, Winter Greening; 10, Cox's Pomona; 11, Royal Russet. *R. J. P.* Wyken (syn. Warwickshire Pippin).—*R. J.* 1, Nonesuch; 2 Small's Admirable.—*W. J. H.* 1, Lady Lennox; 2, Wealthy.—*F. A. W.* Mère de Ménage.

Names of Plants: *A. E. Y.* All the Asters were garden seedlings, and as they are florists' varieties we regret we cannot undertake to name them.—*J. C.* 1, Elaeagnus glabra; 2, Olearia macrodonta.—*W. T.* 1, Cotoneaster microphylla; 2, Abies Nordmanniana; 3, too small to identify; 4, Veronica speciosa var. purpurea; 5, V. speciosa var. alba; 6, V. speciosa var. atropurpurea.—*F. H. F.* Rhus Cotinus, Whig Tree.—*C. P.* We cannot undertake to name varieties of Roses; send specimens to a specialist.—*J. W.* Phytolacca decandra.—*R. M. P.* We do not undertake to name varieties of Michaelmas Daisies; send to some grower who specialises in these flowers. Perhaps Mr. H. J. Jones, Ryecroft Nursery, Lewisham, would be willing to assist you.—*Ride.* 1, Quercus acuta var. bambusaefolia. 2, Abelia triflora.—*Aylwin.* 1, Thuya plicata; 2, Deutzia crenata; 4, Cupressus Lawsoniana; 8, C. Lawsoniana var. ochroleuca. It is impossible to determine the others without flowers or fruits.—*J. H. J. B.* Probably Jamesia americana; send when in flower.—*W. T.* 1, Cupressus sempervirens; 2, Picea orientalis; 3, Veronica Andersonii; 4 and 5, too small to identify; 6, Cupressus pisifera var. plumosa; 7, Osmunda regalis.

Oak from Turkey: *L. P.* The specimen sent is the Kermes Oak, Quercus coccifera, a native of the Mediterranean region from Spain eastwards to Syria. September and early October, and late April or May are the best times to transplant this evergreen Oak. Select showery weather for preference, and move the tree with as much soil as possible adhering to the roots. Syringe the foliage morning and evening on dry days the first few weeks after transplanting. Cuttings only to 2 inches long, made from the ends of the young shoots, will root in a cold frame, or under a handlight placed at the foot of a west wall, during August and September. You may insert a few shoots now, though you will not be successful in rooting a large percentage of them at this late date.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 42.0°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, November 14, 10 a.m.: Bar. 29.9; temp., 45°. Weather—Bright.

The Nomenclature of Cultivated Plants.

The difficulties of naming succinctly and systematically garden plants are great and perhaps insuperable. The impatient are apt to see in any attempt to improve nomenclature the fussiness of pedantry; but those who are aware of the variedly diverse origin of different kinds of garden plants recognise that there is need for a better system of nomenclature and are grateful to anyone who attempts to introduce it. Garden plants fall into numerous categories. Some are true species, the wild prototypes of which are known either in nature or in herbaria. Their nomenclature is decided by the botanist, and all the gardener need ask is that the systematist should not without the most cogent reasons change a specific or generic name which has passed into general usage by gardeners. Other garden plants are sports or mutants of a wild species or of a cultivated variety thereof, and the ordinary practice of adding a varietal name to the binomial would seem to meet their case. A third category of cultivated plants consists of those which are not identifiable with any known wild species. Maize is such a plant. Happily, in spite of its probable hybrid origin, it was named as though it were a legitimate species. Chrysanthemum, Dahlia, Apple, Plum and Peach and many other garden plants are not to be referred with certainty to wild species, nor in not a few of them may their origin be determined. Fortunately they already have their several names, and none will venture to alter them. But other garden plants are of undoubted hybrid origin; many of unknown and many of known parentage. The real problem of nomenclature of garden plants is presented in acute form by them. To style a garden hybrid, "Phlox paniculata x P. maculata, Brand," is to catalogue and not to name it. To call it by a fancy name is better, but that practice has the disadvantage of suppressing all indication as to its origin or parentage. This perhaps is no great matter and many may incline to the opinion that it is the solution of the problem. Yet Orchidists who are every year creating more and more astonishing hybrids, do not accept this method, but make descriptive portmanteau names by combining parts of the parental generic names. The advantage of the method is that it serves to indicate origins; the disadvantage, that the names become, as the hybridist brings new genera into the complex, ever larger and clumsier. The rosarian recognising the desirability of indicating origins, whilst giving a fancy name endeavours with more or less success to group Roses in categories indicative of their real or supposed origins. With wider hybridisation, however, the classification into groups becomes ever more difficult and conventional. It is not easy to suggest improvement on these methods, but it cannot be entirely satisfactory to a gardener to know a plant only by such names as Jessie or even Lady Hillingdon. Where the fancy name made be made descriptive it is obviously an advantage, and such names as Rayon d'Or are preferable to Ophelia or even Irish Elegance. Nevertheless it is clear that descriptive names are often impossible, and even when they can be applied they do nothing to define the plant for which they stand.

Prof. L. H. Bailey* has in the course of his prolonged studies of cultivated plants felt these and other difficulties of nomenclature acutely. He proposes the introduction of certain terms which will, if adopted generally, help matters a little. He would apply the word "cultigen" as opposed to indigen for any plant which is known to have arisen under cultivation. In the case of a *variety* which arose in cultivation he proposes the term cultivar. As to how these cultigens and cultivars should be named, Prof. Bailey appears to be of opinion that except in the case of those which may be designated by the addition of a varietal name, they should receive binomial status. Thus, for cultivated races of Chrysanthemum the wild origin of what is unknown or uncertain, he would propose C. hortorum, leaving it entirely open whether, as has been claimed, C. indicum or C. morifolium or C. sinense, all probably "cultigens," had any part or lot in the parentage of the garden races of Chrysanthemum. Similarly Zonal Pelargoniums he would name Pelargonium hortorum and Show Pelargoniums, P. domesticum. Systematic botanists might not perhaps like the ascription of binomial names to undoubted hybrids, but now that they are becoming less sure of the origins of anything, their objections might perhaps not be so strong as they would have been in former days. In any case it appears that the time is ripe for a conference on the subject of horticultural nomenclature, and in spite of the fact that it is a thorny subject we trust that the Royal Horticultural Society will take steps to inaugurate such a conference with the object of securing agreement as to the method of naming plants of garden origin.

* *Gentes Herbarum*, Occasional Papers on the Kinds of Plants. IV.: Various Cultigens and Transfers in Nomenclature. Ithaca, New York, 1923.

Presentation to Mr. James Whitton, V.M.H.—An especially interesting function was held at Glasgow on November 5 when their colleagues in the service of the Glasgow Corporation entertained four retiring officials to dinner and made a presentation to each. One of the number was Mr. J. Whitton, who recently retired from the position of director of the Corporation's parks and open spaces. Mr. Whitton was presented with an escritoire, and in making the presentation Mr. J. Sutherland observed that Mr. Whitton had latterly 2,700 acres under his care, or five times the area existing when he took charge, while the annual expenditure on Glasgow's parks and open spaces was now nearly six times the amount expended when Mr. Whitton took office.

Dwarf Hawthorns.—According to the *Bulletin of Popular Information*, No. 16, issued by the Arnold Arboretum, some eighty species of dwarf Hawthorns have been distinguished. They are most abundant in Pennsylvania, New York, Ohio and Michigan, occurring so far north as Massachusetts and southward to Alabama. Nearly all the species have large and conspicuous flowers in few-flowered clusters and handsome red or yellow fruit. Many of the dwarf plants are now well established in the Arboretum, and flowers and fruits are produced freely by several of them. Some of these plants are said to be worth cultivating for the beauty of their autumn foliage, which is not surpassed by that of any of the larger growing American Hawthorns. The Arboretum contains a collection of these dwarf plants, at the eastern base of Peter's Hill.

British Mycological Society.—A meeting of this Society will be held in the Botany Department, University College, Gower Street, W.C.1, on Saturday, the 17th inst., at 11 a.m. The programme is as follows:—Miss R. Bracher, M.Sc., "Observations on Rhytisma"; Mr. J. Jackson Clarke, F.R.C.S., "Notes on some Mycological Chromidia"; Mr. W. J. Dowson, M.A., "A Mould attacking Sweet Peas"; Dr. A. S. Horne and Mr. G. H. Jones, B.A., "Further contributions to the study of Eidamia"; Mr. R. Paulson, F.L.S., "Observations on Tree Mycorrhiza"; Mr. A. A. Pearson, F.L.S., "A Foray in Paris." Lunch will be arranged in the College Refectory.

Production of Phosphates in French Oceania.—The phosphate production of the colony of French Oceania, which is composed of the Society, Tuamotu, Marquesas, and scattered groups of islands, amounted, according to the *Journal of the Royal Society of Arts*, to 60,000 tons in 1921. Shipments to the value of over £11,000 were sent during that year to Honolulu, the balance going to Europe. According to the United States Consul at Tahiti, exact figures of the 1922 phosphate output are not yet available, but it has been conservatively estimated at between 80,000 and 90,000 tons. Material to the value of over £26,000 was shipped to Honolulu, the balance having been sent to Europe. The phosphate rock, as shipped, is said by company officers to contain about 80 per cent. of phosphate.

The Potato Crop.—According to the *Monthly Agricultural Report*, published by the Ministry of Agriculture for the week ending November 1, in the Midlands, East and South of England, about three-fourths of the Potato crop had been lifted, but in the North and in Wales this work is not so forward. The weather has been very unfavourable, and the crop is being stored in dirty condition. On the whole, the quality is fairly good, but the tubers are generally small. In most districts the yield is turning out a little better than was expected a month ago, but in Wales the crop has

Digitized by Google

deteriorated considerably owing to the wet, and many tubers are rotting in the ground. The yield per acre is estimated at 5.7 tons, or half a ton less than the ten years' average, and nearly 1½ ton less than last year. On this estimate the total production in England and Wales will be about 2,667,000 tons, against 4,012,000 tons in 1922, and 3,160,000 tons the ten years' average.

Horticultural College, Swanley.—The annual report of the Governors for 1922-23 states that the year has seen the realisation of a further part of the scheme of development started about eighteen months ago, and assisted by the Ministry of Agriculture. The new features include a jam factory of twice the size of the former one, two additional offices, and a new Carnation house. The poultry department has been entirely reorganised; it has been decided to develop this subject further, and to provide special facilities for students wishing to gain a thorough practical and scientific knowledge of poultry husbandry. The development scheme also includes the extension of the reference library by the addition of a large number of books, and of a specially fitted room in which to house them. It is proposed to form an extensive rock and water garden, which will form an attractive addition to the educational facilities, and to the amenities of the College gardens. A third year's course of instruction at the College has been arranged for students working for their diploma. The number of students attending during the year was 80. Scholarships awarded by the following public bodies were held by students at Swanley:—The Central Committee on Women's Training, the Yorkshire West Riding County Council, the Middlesex County Council

The Origin of Petroleum.—A correspondent in the *Times* of the 13th inst. publishes some interesting facts on the formation of petroleum. The evidence, he states, seems to show that whilst coal has been produced almost exclusively from vegetation, petroleum is derived chiefly from marine organisms with a considerable preponderance of animal matter. Accumulations of these marine organisms at the bottom of saline or brackish seas or lagoons have been subjected to decomposition by aerobic bacteria, forming gases and soluble substances. The fats have been subsequently transformed to glycerine and fatty acids, and the presence of salt has modified the ordinary course of decay in the direction of the formation of the petroleum. Some of the deposits of marine organisms are immense; eocene beds in California include a broad area of marine shells more than 4,000 feet in thickness and containing organic matter sufficient for the origin of all the oil in those fields.

High Prices for Floral Books.—At a sale of coloured plate books at Messrs. Sotheby's on the 8th inst., Redouté's *Les Liliacées*, 1807, large paper edition, and *Les Roses*, 1817-24, realised £150 and £55 respectively, while F. R. de Tussac's *Flore des Antilles*, Paris, 1807-27, realised £100.

The Dahlia in America.—The increasing interest taken in Dahlias in America was reflected by the very successful exhibition of the American Dahlia Society, held in New York on September 26-29. Community Dahlia societies made several very attractive entries; there are twenty-eight local Dahlia organisations which are affiliated with the American Dahlia Society. So successful was the show that it is very probable that the Society will rent the great Central Palace in New York for next year's exhibition. Mr. Richard Vincent, Junr., has been re-elected president of the Society.

New Chrysanthemums.—Ample evidence of the activity of raisers of Chrysanthemums was given on the occasion of the recent exhibition of the National Chrysanthemum Society, when no fewer than seventy new varieties—practically all seedlings—were submitted to the judgment of that Society's Floral Committee. Further evidence was forthcoming on Monday, November 12, when the N.C.S. Floral Committee sat in judgment on fifty new sorts and awarded sixteen First-Class Certificates and four Commendations. Not only have novelties been numerous, but on the two occasions cited the high general quality of the flowers was the subject of general comment among growers. Apparently the old florists' spirit is dead, or submerged, on the R.H.S. Floral Committee, for this body granted only four Awards of Merit on the 13th inst, although it had before it a large proportion of the Chrysanthemums which secured the approval of the Chrysanthemum specialists on the previous day.

Mr. W. Clark.—The superintendent of the Public Parks and Open Spaces of the enterprising seaside town of Southport was born at Bannerfield, Selkirk, where his father has held the position of gardener to F. S. Roberts, Esq., for forty years. Mr. W. Clark served his apprenticeship under the late Mr. Wm. Fowler at Mertoun House, St. Boswells, then the residence of the late Lord Polwarth. His apprenticeship lasted three and a half years, and then he went as journeyman in the gardens of Dalkeith Palace, the residence of the Duke of Buccleuch, where he served under Mr. James Whytock for about three years. On leaving Dalkeith he became foreman under Mr. A. Brookfield, at Taymouth Castle, Perthshire, then the residence of the late Marquis of Breadalbane. After a short period spent in this position he took charge of the gardens at Auchmore House, Killin. Three and a half years later he came south, and in May, 1910, became foreman under Mr. N. F. Barnes, at Eaton Hall, Chester, where he had special charge of the pleasure grounds and the extensive alterations then being carried out at Eaton Hall. In August, 1914, he joined the Army, and served in France with the Black Watch from May, 1915. In May, 1917, he won the D.C.M., and in October, 1918, was awarded the Belgian Croix de Guerre. In November, 1919, he returned to Eaton Hall, but in the following March was appointed Assistant Park Superintendent of the Southport Corporation, and on the retirement of Mr. J. Hathaway, in December, 1921, was appointed Superintendent. Mr. Clark has made a great feature of the floral displays at Southport, where an herbaceous border half a mile long is a very fine and already greatly famous feature. As our readers are already aware, Southport Corporation is promoting a large horticultural exhibition to be held in one of its parks towards the end of August next.

MR. WILLIAM CLARK.

Town Planning.—In connection with the Commercial Motor Transport and Roads Development Exhibition, to be held at Olympia from November 22 to December 1, a Town Planning Conference has been arranged. This will be held on November 30, under the auspices of the National Housing and Town Planning Council, the Garden Cities and Town Planning Association, and the Town Planning Institute. The subjects discussed will be, at 11 a.m., "The Importance of Town Planning Schemes in Relation Particularly to Arterial Roads Construction and the Relief of Unemployment," and, at 3 p.m., "Regional Town Planning in Relation to Industrial Development." Models demonstrative of town planning schemes, with special relation to road schemes, have been loaned by Birmingham, Manchester, Liverpool, Leeds, and other large city corporations for this conference.

Treacherous Elm Trees.—That Elms are treacherous trees is fairly well known to horticulturists, but not so well known to the general public. As large limbs of old Elm trees may fall without the slightest warning, it is important that trees in positions where the public resort should be lopped to prevent loss of life. A fatal example of this sudden collapse occurred at the West Hertfordshire Golf Club, Watford, on Saturday last, when a player was killed by a falling branch and his wife severely injured.

Agricultural Credits.—In a written reply concerning agricultural credits, Sir Robert Sanders, the Minister of Agriculture, states no agricultural credit societies have so far been formed under the Agricultural Credits Act, and therefore no direct applications for advances under Section 2 of the Act have been received.

Proposed Tax on Imported Apples.—In view of the suggestion in some quarters that a tax of 5s. per hundredweight should be imposed on all foreign Apples imported into this country, the United Fruit and Vegetable Section of the National Federation of Fruit and Potato Traders' Associations has passed the following resolution:—"Resolved that this meeting of the United Fruit and Vegetable Section (Import and Export), representing importers and wholesale and retail dealers in fruit, protests against the proposal to impose a tax on food, namely Apples, and against putting forward such a proposal without any consultation with the fruit trade. This meeting requests that nothing further be done without a full discussion with representatives of the trade from the chief centres of importation—Liverpool, London, Glasgow, Manchester, and Hull." It was argued that, as the bulk of the exportable crop of Canadian Apples was sent to this country, and that Australasian Apples did not compete to any great extent with American Apples, the only effect would be to increase the price of Apples from the United States by 25 per cent. to 50 per cent. The support of the Scottish Retail Fruit Association and of the Hull Fruit Merchants' Trade Protection Society against the tax was announced by the secretary. The Committee of the United Fruit and Vegetable Section of the National Federation of Fruit and Potato Traders' Associations resolved to forward the resolution to the Board of Trade, and has appointed an emergency committee to deal with the matter.

Horticulture and Agriculture at Cambridge University.—The annual report of the Board for Agriculture and Forestry states that during the recent year 284 students presented themselves for the examinations in agriculture, estate management, and horticulture, and sixty-six per cent. of those who entered passed. The Board records that the work of the students was of a very high order. Mr. R. E. Priestley, fellow of Clare College, has been appointed lecturer in soil chemistry, Mr. E. T. Halnan has taken charge of the newly formed poultry section, Mr. A. Watkins and Mr. H. Hunter have been attached to the plant breeding institute, and Mr. W. A. R. Dillon Watson is associated with Mr. Petherbridge as mycologist to the department. Two notable events have taken place during the past year—namely, the completion of the purchase (with Government assistance) of the University farms and the appointment of a Professor of Animal Pathology.

Digitized by Google

The Best Twelve Early-flowering Chrysanthemums.—During the progress of the extensive trial of early-flowering Chrysanthemums just concluding at Wisley, members of the Garden Committee were deputed to select the twelve varieties which, in their opinion at the time they saw the trials (when most of the varieties were in full bloom), were the most desirable for growing in the majority of gardens. Their choice fell upon the following:—(White) September White and Candida, sent also as Sanctity and Excelsior; (Pale yellow) Framfield Early Primrose, sent also as Southover Yellow and Willington Early Yellow; (Yellow) Hollicot Yellow, sent also as Goldfinder and Philip; Horace Martin, sent also as Elstob Yellow and Maggie; (Orange-yellow) Golden Almirante, sent also as Vinstone Bronze; (Bronze) Mrs. Jack Pearson and Bronze Goacher; (Chestnut) Almirante; (Chestnut-crimson) Red Almirante, sent also as Alcalde; (Pink) Normandie; and (Purple) Lichfield Purple).

Croydon Horticultural Society and Entertainment Tax.—The accounts of the Croydon Horticultural Society for the year 1923, presented at the annual meeting held on November 5, show that the Society has a deficit balance of £65 9s. 3d. Subscriptions for the year amounted to £93 6s. 6d., the total receipts for the year being £594 19s. 1d. Unfortunately the Society had to pay entertainment tax amounting to £65 16s. 6d., which accounts for the deficit on the year's working. Alderman W. B. Southwell was elected president for 1924 and Mr. W. E. Bream was appointed to succeed Mr. L. R. Welstead as Secretary. Mr. Welstead, who has been a prominent member of the Society for over forty years, was very heartily thanked for his long years of faithful service as Secretary.

Honour for a French Gardener.—M. Opoix, formerly head gardener at the famous Luxembourg Gardens in Paris, has been created an Officer of the Legion of Honour. He retired last year, to the great regret of all—colleagues and students alike—with whom he had been associated.

Appointments for the Ensuing Week.—Tuesday, November 20: Sevenoaks Gardeners' Chrysanthemum Society's meeting. Wednesday, November 21: Ayr Chrysanthemum show; Hull and East Riding Chrysanthemum Society's show (2 days). Thursday, November 22: Royal Botanic Society's meeting; Wargrave and District Gardeners' Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Royal Albert Rhubarb.*—Wm. Mitchell begs to call attention to the above excellent variety, which still retains its supremacy over all other sorts hitherto produced, being from two to three weeks earlier than any kind now grown. It has other qualities eminently entitled to notice; it is most delicious in flavour, of a bright red colour, a most prolific bearer and free-grower, with large fleshy stalks, and for early forcing is more suitable than any other variety. Specimens of this splendid vegetable have been inspected and highly approved of by Her Majesty, by whose commands it has been introduced into the Royal Gardens, Windsor. Also Mons. Soyer, of the Reform Club, and other eminent judges, have declared this Rhubarb to surpass anything of the kind ever eaten, and all the principal growers attending the London markets have pronounced it to be by far the best in cultivation. In addition, *W. M.* begs leave to observe that this Rhubarb is the same as was sold so early last season in Manchester, Birmingham, Liverpool, Cambridge, Brighton and other large provincial towns, where it gave universal satisfaction by its extreme earliness, quality, and beauty. Strong one-year planted roots will be sent out at the end of October at 2s. 6d. net. Also, Myatt's Linnaeus, 2s. 6d., and Victoria, 9d. each. The usual trade allowances. Remittances requested from unknown correspondents by post-office order, made payable to William Mitchell, Enfield Highway, Middlesex. Post Office, Enfield.—*Advertisement in Gard. Chron., November* 11, 1848.

Publications Received.—*A Report on Gooseberry Diseases in East Sussex.* East Sussex County Council, County Hall, Lewes.

THE BULB GARDEN.

CALOCHORTI.

THESE lovely Californian bulbous plants, popularly known as Butterfly or Mariposa Tulips, deserve a place in every hardy flower garden, and are particularly suitable for planting in open, sunny positions at the top of the rock garden where the soil is well drained. They throw up their beautiful, cup-shaped flowers in June and July, and for delicacy of texture and brilliance of colour they can scarcely be surpassed.

October and early November is an excellent time for planting, and the bulbs should be put 2 inches or 3 inches deep, and about 4 inches apart. The soil should be well prepared to a good depth, and enriched with a sprinkling of bone meal.

FIG. 103.—CHRYSANTHEMUM MRS. T. HANCOCK, R.H.S. AWARD OF MERIT, OCT. 30 (SEE P. 269).

It is good practice to plant in such a position that the bulbs can be protected against excessively heavy winter rains by a sheet of glass; but this should be removed as soon as growth becomes active in spring. After the flowering period the same protection may again be given if the rainfall is heavy, as, whether the bulbs are lifted or left in position, it is essential for future flowering that they are ripened perfectly. *W. Auton.*

MUSCARI "HEAVENLY BLUE."

I WOULD like to draw attention to this early-flowering bulb. It was introduced from Asia some years ago, and if grown in a mass, as it should be, it presents, when in bloom in March or April, a most beautiful effect in a rich, dark blue, like to that of an Italian sky. But it has to me a greater charm than this, for it is deliciously scented and well adapted for cutting, as the flowers last well in water. It is no trouble to grow, and seems to increase rapidly in almost any situation. The present is a suitable time for planting.

SCILLA PERUVIANA.

THIS fine plant was introduced from Spain about the beginning of the 17th century, and was known by old gardeners as the Hyacinth of Peru, although probably it is a native of Europe. Old John Parkinson, who knew the plant well, states that a severe frost in 1607 killed all his roots of this Squill, so he made a journey to Spain in order to renew his stock, which was an adventure not lightly to be undertaken in those days. He found the plant in full bloom in meadows near Cadiz and making a fine sight. Thus it is most probable that Spain is its native home.

The ordinary kind grows some eight or nine inches high, and bears dark blue flowers, but there is also a white variety not so decorative or showy and not known so well in cultivation. The foliage pushes through the ground with the advent of the autumn rains and remains green throughout the winter. The flowers are numerous and arrayed closely around the stalk in a pyramidal form; as fresh flowers are constantly opening, its flowering season, which is usually in May, lasts for some considerable time. The plant is said to be not quite hardy, but I have never given it any protection, and although I have it growing in heavy soil that is not well drained, it does not suffer either from frost or continued rains. A light, sandy soil, well enriched with old manure, and a sunny position, would probably be more suited to the plant. The bulbs are about the size of those of an ordinary Daffodil, and increase readily. The secret of obtaining good blooms appears to lie in a thorough ripening of the bulbs. Thus, if this Squill is planted in a hot, dry situation such as is afforded Iris stylosa and Amaryllis Belladonna reasonable success may be expected. *T. D. T.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. Barker, late Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

Miltonia.—Miltonias of the vexillaria section and their hybrids, which were potted soon after their flowering was over, will now be in active growth, and rooting freely. Being well established in the new material they should have water afforded them whenever the compost becomes dry. Care should be taken that the water is not colder than the temperature of the house in which they are grown, as there is a danger of the roots suffering, and the plants getting a decided check if cold water is given them. Although strong sunlight during the summer causes the foliage to put on a sickly hue, at present the plants should be grown near to the roof-glass. This will prevent the leaves becoming drawn and attenuated; the cultivator should endeavour to produce short, robust growths, which will produce flowers of the best quality in the proper season. A moderately moist position in a Cattleya house, or a house of the same temperature, should be selected for Miltonias, and their surroundings should be kept humid, but too much water should not be applied direct to the compost during the dull days of winter. No attempt should be made to hasten the plants into rapid growth, but keep them growing steadily.

Autumn-flowering Miltonias.—The autumn-flowering varieties of M. vexillaria, such as Leopoldi and superba, with any of the hybrids which have just passed out of bloom, may be repotted, if the young growths are of sufficient strength and about to develop new roots. Should the growths be weak and the plants small this operation is best deferred until the spring, when the longer days and the more genial atmosphere will be more conducive to satisfactory growth. The form of M. vexillaria, known as robusta, flowers later than the type, and may be treated like the autumn-flowering varieties. Some of the hybrids are irregular in their flowering season, and may have new compost given them whenever the young growths are in the desired condition. Failure with these plants is often attributable to the compost being allowed to become sour and decomposed. Should cold weather prevail, necessitating the use of much fire heat, a strict watch must be kept for yellow thrips and other insect pests, which are very partial to these plants, and will soon disfigure their thin and delicate leaves if not eradicated. Although the flowers of these plants are not much used as cut blooms, the plants themselves are most useful for indoor decoration, where their flowers will last for a considerable time, without any harm accruing to the plants, especially if they are watered carefully.

HARDY FRUIT GARDEN.

By A. J. Hartless, Gardener to Major J. F. Harrison, King's Walden Bury, Hitchin, Hertfordshire.

Pruning.—This work should be proceeded with as weather and opportunity permit. Bush trees should have their leading shoots shortened two-thirds their length. Those left for extension (during the summer pruning), and to replace some of the taller main stems, may be reduced to the riper part, and the old stems cut away. Although extension shoots should, if possible, be selected growing at the same angle as the old stem, a shoot with a bad curve will straighten itself on all trees except Conifers, the woody tissue of the inside curve growing about three times as fast as that of the outer surface. In training young bush trees careful selection of permanent shoots should be made. Allow them plenty of room in order that light and air may enter the tree freely. Lateral shoots should, if not already done, be reduced to two or three buds. Spurs should not be encouraged to grow too closely together, and on older trees a reduction in the number should be made annually, necessitating, as a rule, the use of a saw. All saw wounds should be trimmed carefully with a sharp knife, and gas tar or tree styptic painted over them.

Bush Fruits.—These become rapidly exhausted if attention is not paid to them, and easily succumb to attacks of "die back" disease. A liberal supply of rotted manure should be at hand. The preparation of this can be done when unfavourable weather does not permit of ground operations. It is better, if it can be done, to prune and clear the ground before the manure is put on the land, and it may be wheeled to where it is required in frosty weather. In pruning bush fruits encourage extension shoots to develop to furnish the tree with young, vigorous branches. Black Currants need a somewhat different treatment to the Red or White Currant. The pruning of the Black Currants consists chiefly in reducing the old fruiting shoots as much as possible, and encouraging shoots of the previous year's growth from the base. These plants are gross feeders and require plenty of nourishment. It is often desirable, especially in woodland areas, to defer pruning Gooseberry bushes until late in the spring, because of the fondness of birds for the buds of these fruits.

Silver-leaf Disease.—Where silver-leaf is suspected the fungus (Stereum purpureum) may often be found at the base of the tree during November. Affected trees should be burned, also the soil around them to the depth of 2 inches.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Winter-flowering Begonias.—Plants in flower, if used for greenhouse or conservatory furnishing, should be given a position at the warmer end of the house. This observation applies to the Gloire de Lorraine varieties, as well as the hybrids resulting from crossing Begonia socotrana with the tuberous-rooted varieties. The latter are well represented at present by such fine sorts as Mrs. Heal, Fascination and Exquisite. The variety Mrs. Peterson, which belongs to the Lorraine section, has dark foliage, and is very effective for house decoration, showing up well under artificial light. It is rather slow growing, therefore it is a good plan to propagate it now, either from cuttings or leaves; the present is a better time to use leaves for propagating than after the flowering period.

Columnea.—The Columneas include a number of beautiful species and hybrids which are very useful for the stove or intermediate house. C. gloriosa and its variety purpurascens have been flowering with wonderful profusion for some weeks; the large orange and scarlet coloured flowers seem out of all proportion to the slender, drooping shoots they are produced on. This species and its varieties are best grown in Orchid baskets, using a compost of rough fibrous peat and loam, with charcoal and silver sand added to render the compost open. Some of the stronger growing species are best grown in pots, using a similar compost to that just recommended. C. magnifica is best grown in cooler conditions, and when in flower stands quite well in an ordinary greenhouse; while C. Lemoinei also succeeds under the same conditions. The hybrid C. Banksii needs an intermediate temperature. All the Columneas are easily propagated by means of cuttings dibbled in a bed of fibre and sand with slight bottom heat. Most of them may also be propagated by dividing the stems into short sections and using them as cuttings.

Episcia fulgida.—This plant, with its beautiful foliage and brilliant red flowers, is very useful for decorative work. Well grown specimens in small pots or pans are very suited for table decoration; while large plants in pans are suitable for furnishing the stages in the stove. The plant may also be grown in small baskets. It is easily propagated at any time by means of cuttings inserted in pots of sandy soil, and stood in a warm propagating case. A regular supply of plants may be had by putting in successional batches of cuttings.

THE FLOWER GARDEN.

By G. Turner, Gardener to Emily, Lady Ampthill, Ampthill Park, Ampthill, Bedfordshire.

Transplanted Seedlings.—Biennials and perennials not yet planted in their flowering quarters, nor likely to be before the end of the year, should be cleared of weeds and decaying foliage, and the surface soil loosened between the rows—the latter work should be done with a fork where the ground is too stiff to use the Dutch hoe. Where slugs are troublesome the rows should be dusted with well-seasoned soot or old lime from time to time. Given open weather and a workable soil it pays to get as many of these plants as possible in their permanent places before the New Year, for they certainly do much better than when left until the spring before transplanting them. It is not, however, always practicable to do so.

Paeony and Iris.—The foliage of the first-named is entirely dead and may be cleared away, afterwards pointing over the beds to make them tidy. Iris plants, being more or less of an evergreen nature, must not be so treated, but simply have the decayed part cut off. Owing to their spreading habit of growth and rooting, the forking of the border should be done lightly to prevent unnecessary injury. Most Irises are so good natured in their behaviour that no fear need be entertained in dividing or replanting them where this is desired.

Sedum spectabile.—This plant stands almost alone amongst herbaceous subjects both as regards the nature of its growth and the colouring of its flowers. The flatish corymbs of rosy blossoms provide one of the best effects in the border in autumn, beside which they last long in good condition. This Stonecrop is easily increased by division after flowering, and will grow well in most soils.

Lily-of-the-Valley.—The foliage having died, beds of Lily-of-the-Valley should be made tidy, the soil forked over, and then given a mulch of old manure. If a new border is to be made and planted, work in similar material during its preparation. Plant in rows, spacing the crowns about 2 inches apart, and give a covering of old leaf-mould afterwards. For successional purposes it is a good plan to plant some crowns in a warm, sunny place, and others in a cool and shady situation. Old plants are amenable to lifting and replanting, but in so doing the weedy growths should be discarded, planting the best pieces only.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to J. A. Berners, Esq., Woolverstone Park Gardens, Ipswich.

Early Peach House.—Where ripe Peaches and Nectarines are required in April the house should be closed towards the end of this month. If the pruning, etc., has not been done already—as advised in a previous calendar—the work should be attended to at once. When pruned, untie the trees from the trellis, and tie the shoots into bundles, as this permits ready access to the roof for cleansing the woodwork and glass, or, if on a back wall, for limewashing. If the trees are troubled with scale, the bearing wood should be carefully sponged with an insecticide, and the old wood cleansed with a brush previous to its being bundled. It is a good plan to spray the trees with an insecticide before sponging them, as the pest is then the more easily removed. For a slight attack of red spider hot water applied at a temperature of 150° will be sufficient to clear the trees; but if seriously infested use paraffin emulsion, repeating the application before tying the trees in position again. When doing this work leave sufficient space for training in young wood without danger of the leaves overlapping each other; for the same reason it is advisable to allow rather more space between the shoots on trees trained on a back wall. Due allowance for increase of growth must be considered; young, vigorously-growing trees are often seriously injured by tying the shoots too tightly. Clear the surface of the border of any rubbish, and examine the soil and roots; if these are found to be satisfactory, simply remove an inch or two of the sur-

Digitized by Google

face soil, and apply a top-dressing of good loam mixed with old mortar rubble and wood ash. Old, established trees will be benefited by a dressing of a suitable artificial manure. Any necessary transplanting should now be done, and, where a reserve stock of home-grown trees is available, these will, if carefully lifted and replanted, give a crop of fruit without detriment to the future well-being of the tree. Newly-planted trees should receive a thorough soaking of water at the roots, and be allowed time to settle into position before securing them finally to the trellis. It is advisable, when starting the trees, to close the house for a week or ten days without using fire heat, weather permitting, and then apply sufficient artificial warmth to maintain a night temperature of 45°, with a rise of 10° during the daytime; if the days are bright dispense with fire heat as far as possible, closing the house early to conserve the sun heat. Damp the trees, paths, and walls at the same time. During the early stage of forcing guard against an excess of atmospheric moisture, as much moisture in the air tends to force growth before the flowering period is over, and disbudding cannot be properly done without danger to the embryo fruits. Admit air when the temperature of the house rises to 60°, but prevent cold draughts. If the borders require water give them a good soaking.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Celery.—Late batches of Celery should by now be earthed up finally; if any remain to be done, take full advantage of fine days to complete the work. The soil at the final earthing should be placed well up to the bottom leaves, and the sides of the ridges made firm with the back of the spade to facilitate the throwing off of winter rains and snow. Any plants that have been blanched with brown paper still remaining undug should have rough straw or litter placed around them in the event of sharp frosts, or they may be lifted and heeled in in some convenient corner.

Seakale.—Young roots of Seakale that were planted out in the spring for forcing purposes may now be lifted, and four or five put in an eight-inch pot, covered with old potting soil made fairly firm, and brought into a mushroom house or shed, where they can be kept in absolute darkness. These young roots should not be forced too hard. If early produce is desired, it is better to dig up roots that have been growing two years in the open, as these will naturally throw stronger heads. The permanent plants in beds out-of-doors may be forced by placing Seakale pots over the crowns, and filling between these with leaves and stable litter, well trodden down as the work proceeds. This fermenting material may get very hot in the centre, and if this happens, the lids of the pots should be raised slightly to allow the moisture to escape. Two beds of plants should be grown for this method, forcing them in alternate years. Growing roots and lifting them for forcing under cover is much the best system, as one has the produce under better control, and the flavour of heads forced indoors is also superior.

Garden Paths.—Now is a good time to attend to garden paths that require renovating, and also to make new ones. Loosen the surface with a pickaxe, and remove any rough stones before placing the new gravel in position. In doing so, take care to keep the middle of the path an inch or two higher than the sides. Roll the gravel firmly, and if any wheeling has to be done, place some nine inch boards on the paths, so as not to injure the surface. If new paths are to be made, attention must be paid to efficient drainage by placing some four-inch drain pipes well under the surface along one side of the path with iron trap drains at intervals. The foundation of such paths may consist of clinkers from the stokeholds, brickbats, and other rough material. On the foundation place rough stones, finishing with good binding gravel.

INDOOR PLANTS.

ANTHURIUM.

PRIOR to the introduction of A. Scherzerianum (The Flamingo Plant) from Costa Rica, and A. Andreanum from Columbia, with the ornamental-leaved species A. Veitchii (see Fig. 104), A. cristallinum, A. illustre, A. Warocqueanum, and others in the sixties and seventies of the last century, Anthuriums were very little cultivated except in botanic gardens, as they were considered of very little value to horticulturists for the decoration of the plant houses or other decorative purposes. Since that date the flowering type has been much improved, both in size of spathe and colour, by careful selection and fertilisation. The spathes of the different varieties of A. Scherzerianum are of various shades of colour, including delicate rose, deep coral red, pink, rose carmine, and white, and differ greatly from the bright orange-red of the small spathes of the type. The Anthuriums have not proved very amenable to hybridisation. An interesting hybrid was raised between A. Scherzerianum and its white variety album; the progeny had white spathes spotted and freckled with red, and was named A. Rothschildianum. The finest and most distinctly spotted were again selected and fertilised with their own pollen, the hybrids of this cross including some extra fine spotted varieties of rich colours; some were very heavily spotted, whilst others had a creamy-white ground dotted with fine spots. Many choice varieties have been raised and put into commerce by fertilising a plant with its own pollen, and selecting the finest and best of the seedlings. Amongst them is A. Wardianum, one of the finest and still one of the best of the scarlet-spathed varieties. The foliage is very distinct, and can be easily recognised amongst any other Anthuriums. A. Madame Dalliere and A. Parisiense have bright rose-pink coloured spathes. A. Duvivierianum is by far the best white variety, and it forms a splendid contrast to the scarlet sorts. A. Le Flambeau has a spathe of deep crimson colour, and is very distinct. A. album is a white variety with yellowish-white spadix. A. Souvenir de Louis de Smet has an extra large and round spathe; it is a splendid variety. Large numbers of fine seedlings have been raised from time to time, and put into commerce without having any distinctive name given to them.

All the members of the A. Scherzerianum type do well in a moist atmosphere, and a temperature of about 60°. When in flower they may be grown in a lower temperature in the conservatory, or used for indoor decoration. They provide a mass of gay colour and are a great feature in groups at flower shows. The spathes are invaluable as cut blooms, and last a very long time when cut, for all kinds of decorative purposes.

A. Andreanum is an extremely beautiful species, quite distinct from A. Scherzerianum, with rich scarlet spathes and yellowish-white spadix. This species requires a higher temperature than A. Scherzerianum.

Numerous varieties and hybrids of this plant have been obtained, some of which are distinct, whilst others are of no commercial value. Amongst the best are album, with a pure white spathe, one of the most effective of the type, delicatum having a beautiful delicate rose-coloured spathe; giganteum, with an extra large brilliantly coloured spathe; atrosanguineum, dark coral-red, one of the finest dark red varieties; A. Ferrieriense, a strong growing hybrid from A. ornatum, with white spathe and purplish tinted spadix. It was introduced from Venezuela. This plant is a strong grower.

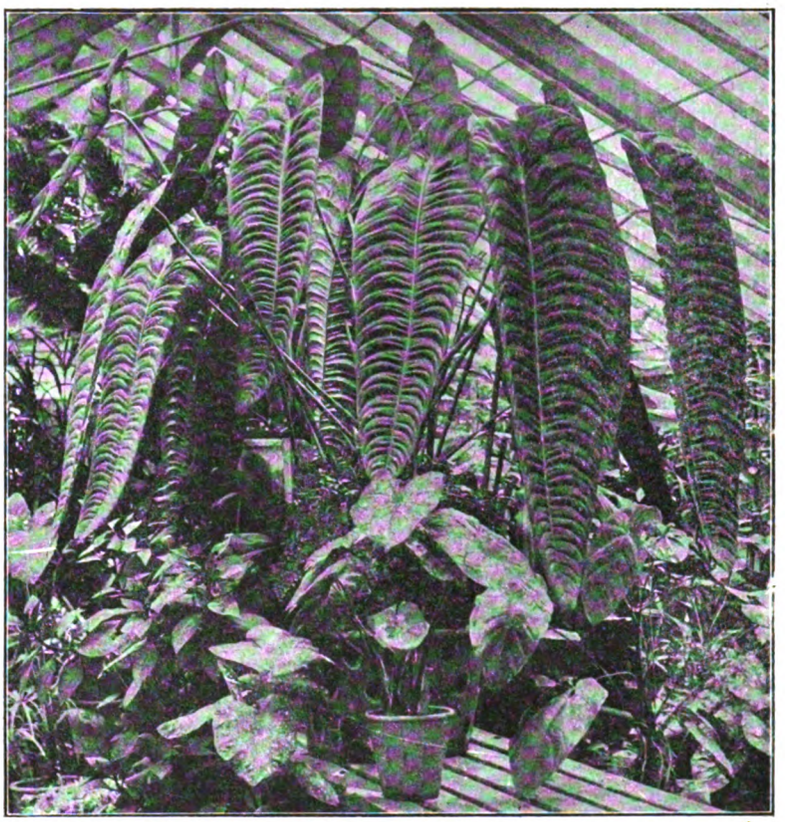

FIG. 104.—ANTHURIUM VEITCHII, ONE OF THE LARGEST-LEAVED SPECIES.

The following crosses are of no commercial value:—A. Andreanum × spathiphyllum Minahassae (commutatum). A. Andreanum × A. Scherzerianum Wardianum. A. album × own pollen, A. Ferrieriense × Andreanum, A. Ferrieriense × spathiphyllum Minahassae.

The members of the A. Andreanum type thrive well in a moist atmosphere and a temperature ranging from 65° to 70°. The spathes are greatly in demand as cut "flowers" for filling large vases, and other decorative requirements, on account of their lasting properties.

The ornamental-leaved species are unequalled for the beauty of their noble foliage, but are not suitable for indoor decoration owing to their

Digitized by Google

delicate texture, as they suffer very much when subjected to a dry atmosphere, or draughts, but where suitable accommodation can be found, they present a very attractive and ornamental appearance amongst any collection of plants. The inflorescence is insignificant, but the foliage is superb.

Amongst the most admired are A. Veitchii (Fig. 104), a magnificent Aroid, and without doubt the finest and noblest of all, the leaves often attaining a length from 4 feet to 5 feet, with a breadth of not less than one-third of these dimensions. The waved appearance of deep green with a brilliant metallic lustre adds to the beauty of the foliage.

A. Warocqueanum is a magnificent species with leaves 3 feet to 4 feet long, of rich deep velvety green, with a light green midrib and secondary veins. A. cristallinum is a very striking plant; it grows dwarf and compact, and has leaves of rich dark olive-green, with the principal veins elegantly banded with silver. A. illustre has creamy-white leaves in various forms. A. magnificum is a handsome species, with large, richly coloured leaves, marked with white, and a silvery midrib along the principal veins. A. Brownii is another noble species, with dark green, shining foliage, on tall stalks. This plant is suitable for growing in a large stove, or conservatory.

All the Anthuriums are of easy culture, provided they are grown in a suitable temperature with a moderately moist atmosphere. They should be repotted when necessary in a mixture of good turfy, fibrous peat, a small quantity of light loam, a little charcoal if procurable, with silver sand added. In repotting the plants use clean pots or pans of suitable sizes, and let them be well drained with good clean crocks, covering the latter with fibrous peat or Sphagnum moss to prevent the fine soil getting mixed with crocks. Press the soil firmly but do not make it too hard. Remove all the loose, decayed soil. Keep the base of the plant well above the rim of the pot, for they will not thrive if potted too deeply in the soil. Light is essential to develop the leaves, but the plants should not be exposed to bright sunshine. When well rooted a covering of thick cushion Moss over the soil is beneficial to the roots; which will penetrate into the Moss until it becomes a perfect mass of roots. Covering the soil with Moss also adds to the smart appearance of the plant. The spring is the best time for repotting. The plants should be syringed two or three times daily in the summer. Be careful not to overwater them, especially after they are potted, or the soil may become sour before the new roots are growing freely. After that stage they will need a liberal quantity of moisture until the end of the summer, when the supply should be lessened, as during the winter months they should be kept comparatively at rest. *John Heal, V.M.H.*

TREES AND SHRUBS.

EUPATORIUM WEINMANNIANUM.

ALTHOUGH not a flowering shrub of the highest merit, this Eupatorium is very useful, as it flowers late in the year, the large, flat clusters of small white blossoms appearing in succession throughout the autumn and often into winter in favourable weather. The heads of bloom, which are nine inches or so in diameter, are fragrant, and may be effectively used for table decoration. They are succeeded by the fluffy seed pappus characteristic of most species of this genus.

This shrubby Agrimony is a rapid grower, with attractive, glossy, evergreen foliage. It makes a bush up to 10 feet in height and as much through, but as it grows freely from the base when cut back in March, it may, if desired, be kept down to a much smaller size. Since it is not hardy everywhere, the frost often nips its unripened wood, thus rendering hard spring pruning desirable. It is said to need the shelter of a wall in the London district, and this is probably advisable in all but our milder counties. A fairly rich, moist, well-drained soil appears to suit it admirably. *N. Wales.*

CYTISUS KEWENSIS.

THIS is one of the best members of the large family of Brooms. It is of dwarf, rather spreading, habit, and covered in spring with creamy-white flowers. Purchasers should, however, be careful to obtain the true form, as some plants sold as Cytisus kewensis are not true to type, having a stronger habit of growth, and flowers of a deeper shade of colour. C. kewensis is an ideal shrub for planting on the top of a rockery or bank, and when its shoots droop over the edge, there is no more effective shrub for such a position. *R. W. Thatcher.*

DEUTZIA WILSONII.

THIS vigorous growing species, introduced from China, has branches which arch gracefully, and are covered in due season with large trusses of pure white flowers. The foliage is large for a Deutzia, long and pointed; the young shoots are pale green, and contrast well with the brown stems of the previous year's flowering-growths. The plant should be staked when young, as rough winds are apt to snap the tender, quickly growing shoots. As soon as flowering is over the old wood should be cut away at the base, and the young growths neatly tied in. *R. W. T.*

THE ROSE GARDEN.

SINGLE ROSES.

SINGLE flowering Roses are very popular for use as table or room decoration, lending a charm of grace and fine effect unsurpassed by any other flower. The prizes for decorations at most horticultural shows prove the great value of this class of Rose, and those with such art shades as are possessed by Irish Fireflame and Irish Elegance, or single Roses with blended colours as Isobel, Queen of the Belgians, and Ethel James, never fail to please. Varieties of deeper colour include Waltham Scarlet, Princess May and Ulster Standard, whilst Yellow Ulster Gem and Mermaid are fine single yellow sorts. White single Roses are rare, and the only variety I have seen really useful is Simplicity.

ROSE ELIZABETH CULLEN.

THIS crimson Rose has been under my notice for a couple of seasons, and I have high opinions of it as a bedder and for furnishing cut blooms. The colour is dark crimson; the buds are long and pointed, and the bloom is deliciously scented. The growth is of moderate strength and the foliage is dark green, making it an ideal bedding Rose; the habit of growth is very regular. The blooms are splendid for use in table decorations. Another great point in favour of this variety is that the colour does not bleach or turn a magenta shade as those of many dark Roses do. It is splendid grown as a bush and equally good as a standard. The flowers are not over full, but it has more petals than either Red Letter Day or K. of K. *G. L.*

ROSE LEONIE LAMESCH.

YOUR correspondent's eulogy (p. 249) of this old Rose is quite refreshing, for it is seldom one hears it praised. I have some large bushes in my own garden, but most people dislike it, and some even go so far as to call it ugly. I remember years ago being told that it was a great favourite with Queen Alexandra, but the general public will have none of it. Evidently it needs special taste to appreciate it! *A. H. Pearson, Lowdham.*

ROSE SOUVENIR DE MME. VERSCHUREN

THIS new Rose is said to have been one of the outstanding features of the California Nurserymen's Association's show. It is the progeny of an unnamed seedling from Sunburst crossed with Golden Ophelia. According to the *Florists' Exchange*, it is one of the finest of yellow Roses, and does well both in the open and when forced under glass. It is said to have the habit of Sunburst, but is more vigorous. The colour of the bloom is cadmium yellow, shading to orange, and the flowers are large, full and of perfect form.

THE IRIS GARDEN.

IRISES FOR SUCCESSIONAL BLOOMING.

THE first Iris to bloom in the New Year is the pretty, dwarf, bulbous Iris alata, which has large blue flowers with a golden crest. This species is followed closely by I. Danfordiae, with golden flowers. In close succession follows I. reticulata, which has rich violet-blue flowers that are delightfully scented.

I. persica has a strange combination of pale silvery-blue and sea-green coloured flowers, which are produced during March and April, whilst I. histrioides is sky-blue, with yellow markings.

The above are charming when grown in pots for the Alpine house, and most effective in the rockery, preferring a sharp, gritty soil, and a sunny aspect, for preference under a warm wall, or in selected pockets on the rockery.

Iris pumila, the Crimean Iris, is a very desirable dwarf-growing species which flowers from March to early May, and it closely resembles the tall Bearded Irises in miniature. Being dwarf, it is well adapted for growing on the rockery, or as an edging to borders. Attaining a height of from six inches to nine inches, I have seen varieties of this dwarf Iris used to good advantage on old walls and ruins, making a very pleasing effect.

Some of the best sorts are Bridesmaid, sulphur-white; Cyanea, violet-blue and purple; lutea; Orange Queen, yellow and orange; Princess Louise, soft pearly-blue; Snow Cup or Schnaecuppe, snow-white; and Statellae, with pretty, globular, creamy-white flowers, which have a most delightful fragrance.

The Intermedia or May-flowering Irises comprise a group of hybrids, the result of crosses between the early-flowering Crimean I. pumila and the tall bearded I. barbata. The plants are of medium height (from 12 inches to 18 inches), and produce large flowers that are sweetly scented. This early Iris has a vigorous constitution, and is well adapted for planting in front of the taller bearded Iris. Brunette, pale yellow; Halfdan, canary-yellow; Ingeborg, ivory-white; Ivorine, pure white; Prince Victor, rich blue; and Walhalla, light blue and purple, are all most beautiful sorts, that will succeed in any well drained sunny border.

The June-flowering, tall Bearded Irises, the most popular group, follow the last closely in flower. Their stately habit, and the gorgeous, regal splendour of the varied coloured flowers, set off by the broad sword-shaped, glaucous leaves, render them most desirable garden plants. They grow from two feet to five feet tall, and will succeed in almost any ordinary ground, yet few plants respond more kindly to well trenched, well worked soil, and if lime is absent from the staple, the addition of a little of this material is very desirable. Their names are legion, and the cost of a few of the new varieties is rather high, but I may mention a few which were noted at a June R.H.S. show, viz., Belladonna, self china blue; Cassandra, rosy-violet and crimson; Dejah, silvery-blue and mauve; Duke of York, blue and mauve; Eden Phillpotts, lavender-blue; George Yeld, Apricot-rose and rosy-crimson; Harpalion, lavender-bronze and blue; Lady Sackville, silvery-blue and violet-purple; Lord Lambourne, a combination of rosy-bronze and madder-crimson; Marjorie Tinley, lavender-blue and mauve; Mrs. Marion Cran, light rose self; Ruby Perry, dark rose; and Troades, old rose and crimson. Less expensive sorts include Albatross, white and crimson-purple; Alcazar, bluish-violet and purple; Ambassadeur, reddish-violet; Aurea and Sherwin Wright, two good chrome-yellow varieties; Bazaria, purple; Benoni, rosy-purple; Black Prince, violet-purple; Caprice, reddish-purple; Clara Curtis, heliotrope and rosy-purple; Edward Michael, wine red; Flamenschwert, yellow and crimson-maroon; Hemodus, lavender-blue; Iris King, old gold and crimson; Jacquesiana, crimson-copper and maroon; Lady Foster, pale blue and bluish-violet; La Tendresse, rosy-white; La Neige, snow-white;

Digitized by Google

Lord of June, lavender and dark blue; Magnifica, violet-blue and reddish-violet; Mdlle. Schwartz, pale mauve; Prosper Langier, copper and crimson; Rhein Nixe, white and violet-purple; Richard II., white and violet; Standard Bearer, reddish-purple, and White Queen.

The best time to transplant the June-flowering Irises, including the Intermedia and pumila varieties, is immediately after flowering, or failing then, during autumn. I have known successful planting operations during spring, the plants flowering well, but growing dwarfer in consequence of late transplanting. It is, however, important to remember that the Pogoniris or Bearded Irises do not thrive in cold, wet soils; they are sun-loving subjects, and should be planted shallowly in well drained soils, although it is surprising what an astonishing amount of neglect they will endure.

In June and July the Xiphium or Spanish Irises give a grand display, and the flowers are highly valued for cutting for table decoration. The new Dutch or large-flowered hybrids are well worthy of attention, their flowers being much larger, the growth more vigorous, and the flowering fully a fortnight earlier than the Spanish type. Iris xiphioides or English Irises are later than the Dutch and Spanish, and thrive in a much colder and wetter soil. They soon become naturalised and bloom well for two to three years, when they may be lifted and transplanted. The colours are very varied in self shades, from white to dark purple, while many are beautifully mottled and flecked.

In July and August the Beardless forms predominate, and are well adapted for growing in the back row of herbaceous borders, in isolated groups in various parts of the border, or for planting by the side of lakes, streams or semi-moist spots, where they are very effective, having handsome grass-like foliage, and tall spikes bearing handsome flowers. A selection of these Irises includes aurea, yellow; Monnieri, deep yellow; orientalis, white; Shelford Giant, white with yellow lip; and Guldenstadtiana. Iris Kaempferi, the Japanese Iris, in many beautiful shades, is splendid for a warm, sunny position by the side of a lake or stream. The Siberian Irises comprise another fine group, and of this species there are some vastly improved varieties, far superseding the old forms, such as Duchess of York, dark violet; Lady Northcliffe, Mrs. Sanders, Nora Distin, Perry's Blue, Purple Emperor and Snow Queen. *W. Logan.*

THE HEATH GARDEN.

A NATURAL grouping of Heaths and kindred plants will give most pleasing results, and if a wise choice is exercised in regard to varieties a continuity of flower may be maintained during the greater part of the year, consequently a well-planned Heath garden is attractive at any season, and for a considerable period of the year it is full of beauty.

If the site for the Heath garden is of an undulating nature, the planter starts with an advantage, but even on flat land a Heath garden may be made very attractive, especially where Pines and Birches exist with which Heaths associate admirably.

The paths in a Heath garden should be of an informal nature, with no suspicion of artificiality, and may consist mainly of stepping stones around which the growth of the dwarfer Heaths should be encouraged.

The arrangement of planting should be such that bold groups of the taller-growing kinds and varieties are placed at irregular distances, with the dwarfer kinds filling the intervening spaces. By this means the flatness of the land is broken and the beauty of the garden increased.

The number of Heaths in cultivation is large, and only a very big planting scheme would include all the varieties that are worth growing, but the following are among the best and include varieties for each flowering season.

Erica australis is a loose, straggling bush reaching a height of 4 ft. or 5 ft. The flowers are rich red and remain in beauty from March to May. Although not perhaps quite hardy in the North, it is perfectly so in the southern counties and is an excellent plant to grow as its loose growth adds variety among those of denser habit.

E. carnea is one of the best of the dwarf kinds; it grows quickly and soon forms a carpet 6 or 8 inches high. Its season of flowering is February to May, during which time its red flowers are most attractive.

E. cinerea, the Common Heath of our moorlands and commons, is a very showy species, which grows from 9 to 12 inches high and flowers profusely from July to September. There are many varieties varying in depth of colour, and all are worth growing.

FIG. 105.—FLOWERING BRANCH OF ASIMINA TRILOBA (SEE P. 295).

E. codonodes is one of the most beautiful of the larger-growing Heaths, and quickly develops into a large bush with plumose branches clothed with bright green leaves. It flowers with great freedom, the blossoms being pink in the bud but white when open. Its normal season is from March to May, but in mild weather flowers may frequently be found in winter.

E. mediterranea is an excellent plant which by a little care in pruning and training may be grown into a noble specimen several feet high and through. It bears its pinkish flowers from March to May. E. m. carnea is the best variety and the best winter-flowering Heath in cultivation. It is a hybrid between E. mediterranea and E. carnea and flowers more profusely than either. This Heath grows to a height of 15 or 18 inches and spreads rapidly. It frequently commences to flower in November and does not cease until May, and during most of this period it is a mass of red bloom.

E. tetralix is a very beautiful and refined species, not uncommon in Britain, but well worth growing. It cannot fight for its existence like many others, but under good conditions grows quite freely, and it should have an open position where stronger varieties cannot crowd it. Its terminal inflorescences of drooping, pale red flowers are very distinct and appear during late summer and autumn.

E. vagans and its varieties are amongst the best of the late-flowering Heaths, their season extending from August till October.

Calluna vulgaris, the common Ling, which flowers with delightful freedom during August and September, has given several varieties which are valuable for autumn display. Among the most useful of these are alba; Serlei and Hammondii, pure white; Alportii, crimson; and cuprea and aurea with copper and golden leaves respectively, these being very attractive in winter.

Daboecia polifolia, the St. Dabeoc's Heath, is exceptionally useful for massing on a large scale. The type bears red flowers and there are white and red and white varieties, thus giving much scope for effective colour arrangements. It usually grows from 9 to 12 inches high, but under good conditions it is sometimes double this stature. The flowering period is a long one, for the first flowers open in May and the plant continues in flower during the whole summer. In the early months the flowers are somewhat sparingly borne, but in August and September the masses of blooms produce a very fine effect, and under favourable conditions the floral display is frequently carried on until November or even December. *W. Autom, Pyrford Court Gardens, Woking.*

MR. KINGDON WARD'S SEVENTH EXPEDITION IN ASIA.*

No. 24.—THE BACKBONE OF THE IRRAWADDY.

AFTER crossing the four rivers which unite to form the 'Nmai-kha, or eastern branch of the Irrawaddy (of which, as already remarked, the Taron is the greatest) there was no more serious climbing left. The whole country is one vast reeking jungle, crumpled into hills and crawling with rivers. A mountain range, nowhere attaining 9,000 feet altitude, still separated us from the basin of the western Irrawaddy; but that would be a picnic. As a matter of fact, we crossed it and descended far down towards the Nam Tisang in the course of a day's march.

It was almost uncomfortably hot in the deep valleys now, the minimum temperature at the beginning of November never falling below 50° F., while the day temperatures exceeded 70° F. in the shade. But the early mornings were chilly, nevertheless, on account of the damp mist. The path, though better than anything we had sampled yet, was not good; and as most of the streams were not bridged, it was a mercy we had brought no four-footed transport. In the rainy season—that is, during eight or nine months in the year—it would have been almost impossible to get along. As it was, the river being low, I was carried over pick-a-back by the natives. The watershed between the eastern and western branches of the Irrawaddy is crossed by an easy pass at an altitude of about 7,000 feet above sea-level. The forest on this range is filled with magnificent trees of Tsuga, Oak and Castanopsis; and the Oaks especially were festooned with Orchids, which were now breaking into flower. A lovely pale purple Pleione, very sweet scented, frilled every tree trunk. Another genus hung out long sprays of milk-white blooms, with chocolate beards. Other trees, noticed here were species of Maple and the usual Stamineum Rhododendron. The pure white flowered epiphytic Maddenii Rhododendron was also common here, forming clots of colour high up in a Babylonian garden of Ferns, Orchids, Aroids and climbing plants.

All the trees were draped with long streamers of pale Lichen, which waved gently to and fro, like seaweed in a tideway. Their trunks were wrapped in Moss.

From the other side of the pass we had a fine view over the endless hill ranges which hedge in the Nam Tisang, one of the two rivers which combine to form the Mali-kha, or western branch of the Irrawaddy; but the plains of Hkamti were buried in the clouds.

However, we were now only nine marches from Fort Hertz, and I walked with buoyant step.

No sooner had we crossed the divide and entered upon the last long descent into Indo-Malaya, than the real climate began to assert itself. It rained. When we camped in the jungle that night fire-flies valsed round us, and insect life generally became active.

On November 9 we went down into the bowels of the sweltering valley. By the streams, within splash of the water, were plots of Impatiens, yellow-flowered and purple, and speckled; there were pink and white-flowered Begonias in flower also, and the gigantic Aeschynanthus grandiflora. Vegetation struggled and strove everywhere; even the leaves of the big trees were crusted with epiphyllous Lichens and Moss. The smooth trunks of the trees, buttressed at the base with radiating plank roots, shot straight up unbranched for sixty or seventy feet. Climbing Palms abounded, and tall Screw Pines, hoisted up on their flying buttress roots. The ground was strewn with fallen fruits, which germinated immediately, or provided food for army corps of grubs. Amongst them were recognisable the broad thin pods of a Bauhinia, the wheel-shaped schizocarps of an Illicium, Nutmegs (Myristica), cones of Michelia, at least six kinds of Acorn, Castanopsis, the winged seeds of Securidaca, and the nuts of various Dipterocarps, with their long, plume-like streamers.

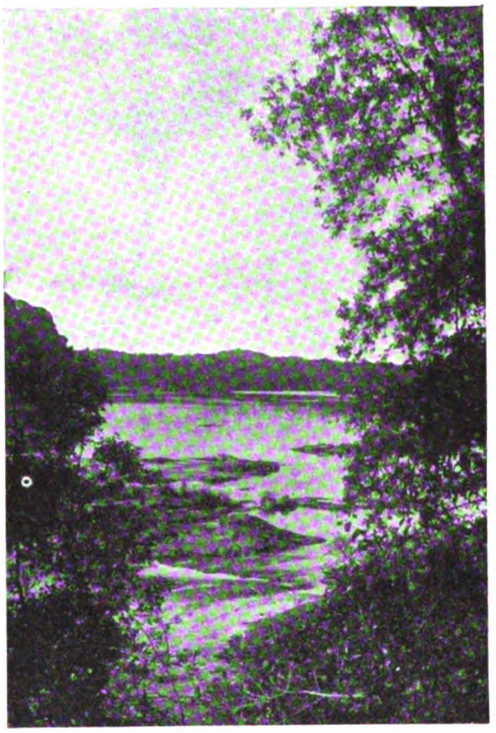

FIG. 106.—THE WESTERN BRANCH OF THE IRRAWADDY, NEAR HKAMTI LONG.

It rained and rained, and the path was an appalling quagmire. Crossing the streams, we picked up leeches, which are the nightmare of the Burmese jungle.

On November 11 we reached the Nam Tisang, and another village. It was four days since we had seen a village; it would be four days before we saw another; so we made a fuss over this one. The Nam Tisang is broad, placid, and at this season shallow. Here we saw endless seas of Bamboo, and wide plains covered with Elephant Grass, and divers Melastomaceae (Osbeckia spp.) and climbing Fern (Lygodium) and Bamboo Orchid.

After crossing yet another range at 6,000 feet altitude, we descended to the Nam Ti, which is the usual rocky jungle torrent. On this range I found Rhododendron vaccinioides in fruit, and collected seed of it. (K.W. 5545.) The seeds are curious—golden yellow, with appendages at each extremity like silken threads, instead of the usual wing. Unfortunately the Rhododendrons met with in this jungle are not likely to be very hardy; this applies only to the half-dozen species met with since leaving the Taron—namely, R. vaccinioides, R. indicum form, the epiphytic Maddenii, the Irroratum (R. facetum?) and the Stamineum.

The epiphytic Orchids at 5,000-6,000 feet were a fine sight, one of the commonest being a white and yellow Coelogyne. A beautiful chocolate Cypripedium was also seen in the forest. Unfortunately rain fell without ceasing and there was no view.

Amongst the forest trees here were numerous species of Garcinia, easily recognised by their milk-white or bright yellow latex (gamboge); several of them had been tapped for the purpose of obtaining this valuable pigment. Beneath one tree I found a quantity of cadmium yellow fruit, and being thirsty (and curious) ate some. Each was about the size of a Horsechestnut (fruit, not seed), and had a soft outer skin, not like the hard outer shell of Garcinia Mangostana (Mangosteen); the seed was inside.

Although the flavour was rather tart, it was quite a good fruit, and no bad effects followed from eating two. I enjoyed them, and indeed marvelled that no one had thought of cultivating them in India or Burma!

It is almost impossible to distinguish the trees in this jungle maze directly—especially in the winter. Recourse must be had to indirect methods. In the hills, an open ridge sometimes enables one to look down on the forest, whence, with the aid of field glasses, some trees may be recognised by their foliage, or habit, or flowers. Similarly the beds of rivers enable one to see tree Ferns, Pandanus, Palms and similar unmistakable types of vegetation. Birds, monkeys, and even insects may furnish valuable clues, though this method requires esoteric knowledge. Some species of Ficus are betrayed thus. Notched trunks from which latex has flowed are useful; better still are fallen trees, which bring down with them climbers otherwise inaccessible, as well as Orchids. But they are not abundant, and often do not fall, being held up by lianas. Flowers may sometimes be picked up; some species bear flowers and fruit at the same time. Fallen branches and cauliflory are invaluable for bringing both flowers and fruit within reach of the harassed collector. But by far the most generally useful and available key to the problem is furnished by the immense numbers of fallen fruits of all kinds which carpet the forest. From these one can at least be certain of the genus, and sometimes of the species.

Of several dozen species of fruit picked up, including, besides those already mentioned, the flattened one-seeded winged pod of a Derris, and the fruit of Sloanea (Tiliaceae), nothing was more astonishing than the cast-iron fruits of a Parinarium—the fleshless Plum of Indo-Malaya.

The thin curved, plate-like embryo is embedded in a shell of the toughest wood imaginable. It is like iron. The "stone"—for the fruit has a thin fleshy jacket—is two inches long, and an inch in circumference. It is rounded at the ends like a sausage. A heavy blow with a hammer just cracked, but did not break, one of these queer Plum stones.

The method of dispersal—for the species are well distributed—is not known. It has been suggested that the fruit, falling like a bullet, and hitting somebody on the head, causes a mild sensation; sufficient at any rate to prompt the victim to pick it up, examine it, and cast it idly aside. The only other method one can suggest—less romantic but possibly, more effective—is that it rolls down the steep hills. "Ah!" you say, "but how did it get up the hills?"

If the method of dispersal is an unsolved problem, the mode of germination appears an insoluble one—short of actual trial. How the embryo ever gets through that half inch armour-plate is a mystery.

After crossing the Nam Ti we marched through the foot hills and in the evening the Hkamti plain burst suddenly upon us. We stood on a ridge which runs out in a long spur to melt down into the plain below. There were sheets of old gold, where the ripening paddy caught the sun, and a broad blade of silver for the western Irrawaddy itself. For miles and miles the plain spread away to more distant horizons, where the mountains began again.—*F. Kingdon Ward.*

NOTES FROM GLASNEVIN

It is many years since we had so much autumn colour at Glasnevin; the display lasted for a month or more and was a source of much enjoyment to visitors. Nearly every deciduous tree and shrub was more than usually attractive in some way, and I find it very difficult to particularise. Among those specially noted, the following are worthy of mention:—Acer platanoides Reitenbachii and A. Schwedleri, bronzy red; A. nikoënse and A. griseum, scarlet; Cercidiphyllum japonicum, golden yellow and crimson; Fothergilla major and F. monticola, glowing scarlet; F. Gardeni, golden yellow; Berberis Thunbergii, bright crimson; Euonymus americanus, cerise pink: and E. atropurpureus, coppery red. Many other shrubs were almost equally good, especially among the vast number of Barberries, named and under number, and now the fruits of Berberis aggregata, B. Prattii, B. brevipaniculata, B. Wilsonae, B. parviflora, B Stapfiana, and others are much in evidence, and will keep the display going for some time.

There is not quite so lavish a display of fruits as usual this year, but Cotoneasters are attractive, particularly C. frigida, C. rugosa salicifolia, C. applanata, and the older species, C. buxifolia and C. rotundifolia. The hips of Rosa Davidii and some of its forms and those of R. Moyesii are of great beauty. Symphoricarpus racemosus laevigatus with its ropes of white fruits is also very effective.

The comparatively mild weather all through October was favourable to many late-flowering, outdoor plants, with the result that we had, in conjunction with the autumn foliage of trees and shrubs, a good display of blossom. One of the most satisfactory plants in this respect is Nerine Bowdenii, of which several forms or hybrids have been planted in the borders adjoining the plant houses. The first plant put out has increased enormously, and this year had thirty-four umbels; others, such as pallida and Exonia planted later, promise to do equally well. No special protection is given to these Nerines; they are planted under the same conditions as the hardy Crinums, which gave a good display in September. The Kaffir Lily, Schizostylis coccinea, and the beautiful pink variety called Mrs. Hegarty, are both flowering freely now in the first week of November. Primula capitata has flowered abundantly all through the autumn, especially the robust form known as P. Mooreana. Crocuses worthy of mention are C. speciosus, C. zonatus, C. pulchellus, C. hadriaticus chrysobelonicus, C. graecus and C. medius. Colchicums flowered profusely, especially noteworthy being C. speciosum, C. speciosum album, C. giganteum, C. Bornmuelleri, C. autumnale plenum, and C. autumnale album plenum, the last-named only fading now.

Indoor Plants.

The Camellia House, so-called because of a number of Camellias grown in the centre bed, together with Rhododendrons and Azaleas, is chiefly given up to batches of popular flowering plants in season. At present Nerines are the outstanding feature. These have long been favourites at Glasnevin, many good hybrids having been raised by Sir Frederick Moore; the collection has also been much improved by the addition of some of the best forms from the collections of the late Mr. W. E. Gumbleton and Mr. H. J. Elwes. A group of Impatiens Oliveri finds many admirers and Plectranthus Mahoni, if not brilliant, is not without interest and provides variety. Cylamens, Primula obconica, Salvia splendens, Salvia farinacea, Balsams and Cinerarias give the bright colour so attractive to the average visitor at this season.

Orchids in bloom are again becoming more plentiful after a more or less quiet time during the late summer and autumn. Among the more showy kinds now in flower may be mentioned Miltonia Leopoldii, Maxillaria grandiflora, Dendrobium Phalaenopsis, Coelogyne Mooreana, and a fine form of Cattleya labiata acquired through Messrs. Protheroe and Morris some years ago, and which is carrying two spikes each of four large, finely coloured flowers; Cattleya×Browniae, C. Iris, C. Bowringiana splendens Cyphers' var., C. Ariel coerulea, L.-C. Canhamiae × Hardyana a very beautifully coloured hybrid presented to the collection by Baron Schröder; Odontoglossum Uro-Skinneri, Vanda coerulea, the latter a plant sent home from Burma by Lady Wheeler-Cuffe; Odontoglossum grande and Epidendrum vitellinum. Among others less brilliant in colour but equally interesting, the following are in flower:—Oncidium incurvum album, Dendrobium Coelogyne, Tainia sessiliflora, Cirrhopetalum gamosepalum, C. ornatissimum, C. Micholitzii, Bulbophyllum occultum, B. Mannii, B. Lobbii, Cochlioda vulcanica, Masdevallia muscosa, and many others of the Chimaera section. *J. W. Besant.*

FIG. 107.—SPECIMEN OF ASIMINA TRILOBA IN THE CAMBRIDGE BOTANIC GARDENS.

PLANTS NEW OR NOTEWORTHY.

ASIMINA TRILOBA.

One of the trees of special interest growing in this garden is Asimina triloba, the American Papaw. The specimen in question is probably the finest in the country, being over 16 feet high and 21 feet through.

The chief interest of this plant lies in the fact that it is the only hardy species of Anonaceae—usually a tropical family; it is the Custard Apple, or Papaw of the Southern, Middle and Western United States of America, and is allied to the Custard Apple and Soursop of the West Indies, although widely different from the true Papaw (Carica Papaya). The usually solitary, shortly-peduncled, drooping flowers with thick, recurved, densely downy flower stalk, are borne during May and June on the previous year's growth, and are about two inches in diameter, yellowish green on first opening, turning to a lurid purple later; they are deeply reticulate and rugose, the six petals being broadly ovate and increasing in length after opening, the three outer ones being the larger, spreading and recurved, while the deciduous sepals are ovate, obtuse and concave (see Fig. 105).

Apart from its interesting flowers, it is quite handsome as a foliage plant; the leaves (which give off rather an unpleasant odour when crushed) are obovate or acuminate, slightly pubescent beneath; the young shoots and leaves are covered with rusty down at first, but soon become glabrous.

The fruits are somewhat bottle-shaped, from three to five inches long, and contain, when ripe, a sweet, yellow, edible pulp.

So far as I am aware no fruit has ever developed on the tree at Cambridge, although it flowers freely in most years. The generic name seems to have been derived from Assiminier, the name applied to it by the early French Colonists of America, and although the plant was introduced from the south-eastern United States so long ago as 1736, it has never become common in gardens; nevertheless, it is well worth growing for its interest, as well as its early flowers and handsome foliage.

Asimina triloba is slow growing when young, but develops into a shapely shrub, or small tree (see Fig. 107). It apparently abounds along the banks of streams in rich soil in its native habitat, and that is the position that suits it in this country, the tree at the Cambridge Botanic Gardens growing beside the pond, and this accounts for the tree doing so well.

Propagation is effected by seeds, when obtainable, or by layers, and as suckers are produced whenever the roots are damaged it would appear that root cuttings offer a ready means of increase. *F. G. Preston, Botanic Gardens, Cambridge.*

SOIL ACIDITY.

THE following observations on the subject of soil acidity may be of value to gardeners interested in soil problems, and, incidentally, may serve to make clear the mode of use and significance of expressions such as "hydrogen-ion concentration," used when soil problems in relation to the growth of plants (see *Gard. Chron.*, Oct. 31) are under discussion.

In accordance with what is known as the "ionization" theory, the view is generally accepted that many chemical compounds, when dissolved in water, break up or "dissociate" into electrically charged particles called *ions*. These may consist of single atoms or of groups of atoms.

Of inorganic compounds—acids, bases and salts—many are almost completely, and others only partially, ionized when dissolved in water; of organic compounds a few, especially acids, are markedly, others slightly, and a few not appreciably, ionized. Water (H_2O) itself dissociates into two kinds of ions—hydrogen-ions (H^+) that carry a positive charge of electricity, and hydroxyl ions (OH^-)—each of which carries a negative charge. Acids, when ionized, yield hydrogen-ions and another kind of ion representing the balance of their constituents; alkalies yield hydroxyl-ions and another ion, consisting in each case of the remainder of the compound.

Observation has shown that the properties of substances commonly classified as acids and alkalies are directly connected with the presence of hydrogen-ions and hydroxyl-ions in their respective solutions. Reddening of blue litmus, the most widely known test for acidity, is produced by hydrogen-ion, and hydrogen ions play an important part in most of the chemical changes in which acids take part. The amount of hydrogen-ion present in a solution is often referred to as the *hydrogen-ion concentration*, and it is evident that this must be a highly important feature of the solution of any acid substance.

Now, the water existing in soil, which, in an ordinary well-drained soil, is present as a continuous film around the soil particles, does not differ in any essential respect from ordinary water. Moreover, all soils contain substances, both organic and inorganic, that are soluble in the soil water, and when dissolved they become ionized to a greater or lesser degree. Some of these substances yield hydrogen-ions in solution, and so give rise to a definite hydrogen-ion concentration in the soil water.

In studying the effect of soil reaction upon the growth of plants, there is good reason to believe that it is of much greater importance to learn the hydrogen-ion concentration of the soil solution than to know the actual quantity of acid which is present at any given moment.

An example may serve to make this statement clearer:—

The usual method of estimating "total acidity" is by "titration," *i.e.*, by the addition of an alkaline solution of known concentration in sufficient quantity to neutralise exactly the acid originally present. Measured in this way, two acids, *e.g.*, citric acid and nitric acid, of the same strength require the same amounts of alkali to produce neutrality in the solutions, *i.e.*, they contain the same total amounts of acid.

The properties of the two solutions are, however, very different; citric acid being what is known as a "weak" acid, and nitric acid a "strong" acid. As already pointed out, the characteristic "acid" properties depend upon the degree of ionization, *i.e.*, upon the proportion of hydrogen ions present. Citric acid, therefore, is a "weak" acid because it ionizes only slightly; nitric acid a "strong" acid because it is almost completely ionized in solution.

Thus, although the total amounts of acid may be the same, hydrogen-ion concentration at any given moment is very much less in the case of citric acid because the greater part is present in the un-ionized condition.

It is known that the effects of acid on the growth of the lower organisms—bacteria, moulds, etc.—is due to the hydrogen-ions present, and there is every reason to believe that the effect of acids on the higher plants is likewise due to hydrogen-ion concentration.

The estimation of hydrogen-ion concentration can be carried out with great precision by means of delicate and elaborate electrical methods. A simpler method, giving results of sufficient accuracy for comparative purposes, is provided by the use of very sensitive colour indicators whose relation to hydrogen-ion concentration has been previously determined.

By the use of this simple colorimetric method, as it is called, a large number of field observations on soil reaction have been made and recorded. A small quantity of soil is either detached from the roots of a pulled-up plant or taken from a known depth, shaken up with a little of the purest water available in a bottle or in a tube and allowed to settle. After decanting the clear liquid into another tube, a few drops of the appropriate indicator are added, and the hydrogen-ion concentration estimated by comparison of the colour with that of the same indicator in a series of "standard" tubes containing solutions of known hydrogen-ion concentration.

Used carefully, the colorimetric method is capable of giving, even under field conditions, definite information as to soil reaction, and thus of providing data as to possible correlation between the distribution of species in different soils in Nature and the hydrogen-ion concentration of the soils in which they are growing.

It must be emphasised, however, that the problems connected with the origin of soil acidity and its effects on plant growth, involve the study of a number of extremely complex phenomena.

The present position has been summarised by Sir John Russell* as follows:—

"The existence of a hydrogen-ion concentration greater than that of water is satisfactory evidence of the presence of true acids in soils. The measurements at present throw no light on the nature or quantity of the acids. . . . They may adversely affect plants or micro-organisms by reason of their strength or their quantity. On the other hand, the acids themselves may be without serious action. The special properties of an 'acid soil' may result from a lack of basicity, whereby:

"1. Special absorption relationships appear;

"2. Lack of calcium may affect plants or micro-organisms;

"3. Certain toxic substances, *e.g.*, metallic salts may remain effective, which in the presence of lime would be thrown out of action.

"4. Clay may become deflocculated, and therefore assume a sticky condition unfavourable to plant growth." *M. C. R.*

* Russell, E. J. *Soil Conditions and Plant Growth*, 1921, p. 113.

MARKET FRUIT GARDEN.

DURING the thirteen years in which records of the rainfall have been kept at my place there has never been such a wet October. There were only eight days without rain, the total for the month amounting to 7.22 inches. The ground, of course, was saturated, and it was difficult to find useful work for the men. Even ploughing was often impossible, so that preparations for planting are delayed. Fortunately, all the Apples were picked before the month was far advanced, and so escaped the gales. As there are indications that the fruit will not keep well, most of it has already been sent to market. Thus a bad season is practically done with, and one's thoughts turn hopefully to preparations for the next.

WHERE TO ECONOMISE.

After such a poor fruit harvest it is necessary to economise, and the question is: In what direction can it be done with least prejudice to next year's prospects? Personally, I have no hesitation in cutting out all winter spraying. There is no certainty that this does anything beyond cleansing the trees of mossy growth, and most of my orchards are clean enough from the work of recent years. Then a good deal of economy in manuring is possible, though one cannot feel quite so happy about this. Manures have been used freely in recent years, and all the trees of bearing age received a dressing of "bud-feeding" fertilisers in August, so they ought to manage without organic manure this winter, particularly as they have not carried a heavy crop during the past season, and in most cases have made plenty of growth. Land that is to be planted with trees and bushes ought to have been dressed with farmyard manure before ploughing; but I shall have to be content with the cheaper method of putting a mulch round each tree after planting.

REPLACING BLACK CURRANTS.

To replace the Black Currants grubbed on account of reversion, I am getting a fresh stock of bushes from Norfolk, where the crop is grown with such success. Most of them are of the old French variety, which is popular in that district; but I am going to plant a small field with Boskoop Giant. This variety had been given up on account of its susceptibility to bud mite, but nothing tried since has equalled it for size of bush and crop on land which is not really well suited for Black Currants. Growers tell me that it now reverts badly, but I fancy all varieties do that.

OFFSET IMPLEMENTS.

The need for economy in labour since the war has stimulated the invention of implements for use in fruit plantations. The plantation plough, with head and handles that can be set off at an angle, so that the horses and man can walk clear of the trees, is now quite an old friend. A cultivator working on the same principle is new, however. I have one, and find it quite easy to manage once the horseman's prejudice against anything new has been overcome. This cultivator has a disc at the rear of the tines, which helps to keep it straight; and there is no difficulty in running it close up to the stems of low half-standards, or even bushes with a short leg.

Another useful implement used by many growers is a spring-tined cultivator with a disc rudder attachment. I have seen this used with great success under quite low bushes, and no implement could be closer to the ground. The object of such implements, of course, is to reduce the work of digging and hoeing to a minimum, and so save expense. Personally, I do not care for ploughing amongst fruit trees more than is absolutely necessary, for fear of injury to the roots. If there is a dry spell in the autumn, in which the ground can be got clean by surface cultivation, there is no need to plough; but when the autumn is wet, like the present one, there is no chance of cleaning operations, and the land is soon green with weeds. There is then nothing for it but to dig or plough. I think it is best to leave the weeds alone for the winter, as they act as a cover crop and prevent the washing away of soluble plant foods, which are returned to the soil, with a good deal of added organic material, if the weeds are turned under the ground in early spring.

SILVER-LEAF DISEASE.

I have always imagined that I was bound, under the Silver-Leaf Order, to cut out all Plum wood carrying silvered foliage, and this has been done every year before the specified date. It appears, however, that growers are not obliged to do this. They are only ordered to cut out and destroy dead wood. This is, of course, sound common sense, because it is only on dead wood that the fungus can fructify and become a danger. In the characteristic silver stage it does no harm, and growers can please themselves as to whether they allow living silvered branches to remain or not. They must decide for themselves which is the wiser policy. Messrs. F. T. Brooks and H. H. Storey, whose research work on this disease is well known, state that it is difficult to give explicit advice on this point. With Apples, in which the rate of

Digitized by Google

natural recovery is high, it is, they consider, generally inadvisable to remove silvered branches unless they are actually beginning to die back. With Plums, the advisability of cutting silvered branches away depends entirely upon circumstances. If certain branches have just begun to be affected, these can often be removed with advantage to the rest of the tree, provided that the wood actually infected is cut away. If, however, the tree is generally silvered, the fungus probably exists in the trunk, where it cannot be excised, and the only sound policy is to wait until the tree begins to die back, or alternatively to recover.

Silvered branches often bear much fruit, and there is no danger of infection from them until they die back. Anything which promotes the growth and general well-being of the tree is considered to encourage natural recovery from silver-leaf, which means that drainage, soil cultivation, and manuring must all receive attention This, with the removal and destruction of dead wood and the prompt dressing of all wounds to prevent infection, is the most we can do at present against this disease. As a dressing, ordinary coal tar is probably best. If applied carefully, it does little or no harm to the surrounding bark. Stockholm tar has been found to be of little use against silver-leaf.

Red Apples.

If there are any pomologists at work in this country with the aim of giving us new Apples expressly for market culture, they ought to make colour the first consideration. It is all very well to talk about educating the public to appreciate flavour disguised under an unattractive skin. The discriminating people who can be appealed to in that way are too few to be worth catering for. In order to compete with the highly coloured imported fruit, we must have red Apples. The only Apple which people buy freely for its flavour is Cox's Orange Pippin. The public do seem to have learned that this cannot be beaten for quality. Apart from this variety, it is colour that scores. There is never the least trouble in selling red dessert Apples at a good price. I have a few trees of Fearn's Pippin which were loaded with fruit this year. This has no flavour except acidity, but it has a brilliant colour. The salesman returned me 10s. per half-bushel for these Apples, one of the best returns I have had this year. Most of the new Apples that are introduced have Cox's Orange Pippin as one parent. The object of most raisers is evidently flavour and quality. Let them aim at colour instead, and I think they might give us some new Apples worth growing for market to compete with imported fruit. Worcester Pearmain naturally suggests itself as one parent, and there are several other red Apples which might be crossed with it. Gascoyne's Scarlet, Ben's Red, Devonshire Quarrenden, Baumann's Reinette, Paroquet, Reinette Rouge Etoilée, and possibly Newton Wonder are some that occur readily to the mind.

Stakes for Fruit Trees.

The wet season (in my district) and high winds have proved very trying to the stakes supporting young trees. Many have had to be substituted by fresh ones. There is a great difference in the lasting qualities of stakes. By far the most satisfactory that I have tried are made from Spanish Chestnut poles, which abound in local woods. But even amongst these there are differences which can hardly be accounted for. In one plantation the stakes lasted until the trees had long outgrown the need for them, and even then could hardly be broken off. In other cases they have needed replacing after a few years. I am told that it depends on the rate of growth of the poles. The best are those that grow slowly on somewhat poor land, and are consequently hard and composed largely of "heart wood." One thing I do know, and that is that creosote is a far better dressing than tar for the points of stakes, giving considerably longer life. The dressed portion should extend above the ground level, for it is just at the surface where the stake is most likely to rot.

A Look Round.

A walk round the farm, now that the trees have been cleared of fruit, makes one hopeful for next season. The trees have made good recovery from the severe attacks of pests and diseases experienced in the spring. Most of them have made plenty of growth, and the leaves are hanging on late. There may, of course, be some doubt as to whether the wood has ripened well, for with me it has been a wet season throughout; there has been none of the drought experienced in many districts. There is a lot of dead wood, due to brown rot, to be cut out of Plums of some varieties, but they have made no lack of new shoots to replace it.

Fruit buds on Apple, Plum, and Pear trees show up conspicuously. Young trees have made plenty of good growth, and are a pleasure to prune. Bush fruits also are full of strong growth, notably Black Currants. *Market Grower.*

FRUIT REGISTER.

APPLE LODDINGTON PEARMAIN.

At the meeting of the Royal Horticultural Society on the 30th ult. Mr. J. George Woodward brought before the notice of the Fruit and Vegetable Committee a little-known Apple named Loddington Pearmain, which is illustrated in Fig. 108. Mr. Woodward stated that he received grafts from which his trees were raised from Mr. Fred Smith, of Loddington, Linton, nr. Maidstone, and he named the variety Loddington from the place of its origin. Mr. Smith was not able to give the parentage, or, indeed, state from whence he had derived this Apple, but it had, in Mr. Woodward's opinion, sufficient merit to warrant its perpetuation, and he raised some trees which are still in existence at Barham Court. Beyond these trees there are, we believe, but few others in cultivation. That so high an authority on fruit as Mr. Woodward should consider the variety worthy of more extended cultivation is high testimony of the merits of this Apple, which might be considered a late Worcester Pearmain, for it resembles that variety in shape and has high colour, but the base of the fruit is marked with a considerable amount of russet. The tree is of erect habit and produces very large leaves. Mr. Woodward informs us that the branches form plenty of spurs and that the cropping is most regular. The size—typical specimens are illustrated—is suitable for dessert purposes, being neither too large nor too small.

FIG. 108.—APPLE LODDINGTON PEARMAIN.

This Apple keeps in good condition until the end of January, but it is best eaten as soon as it is gathered from the tree. Those who enjoy a soft-fleshed Apple will find this variety very palatable just now, but from specimens before us we are inclined to think that kept much longer the flesh would be mealy. The core is of rather small size.

Although Loddington Pearmain will not rank amongst the finest of late dessert Apples, it will appeal to those who desire an Apple of similar size, shape and colour to follow Worcester Pearmain, a variety which is a great favourite with the general public; its fine red colour should satisfy *Market Grower* in his appeal for new market varieties with rich colouring.

APPLE BUSHY GROVE.

ALTHOUGH it was stated in our report of the Royal Horticultural Society's meeting on the 31st ult. that this Apple was included in the trial of commercial varieties at Wisley, we understand that this is not correct.

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

Floral Decorations.—I was pleased to read the note by your correspondent, H. W. Henning (p. 236), on the subject of floral decorations as it applies to gardeners in private service. Mr. Henning is quite right when he states that apparently the only way for young gardeners of the present day to become efficient in this very necessary art, is to take service for a time with some good firm of florists. There is, however, one other source from which a keen and observant young man should be able to gain an insight into at least one branch of this art, namely, table decoration, and that source is horticultural exhibitions. And yet, who would contend that the style of table decorations seen at exhibitions is of any real practical value for the decorator in private service? Excluding the big National Societies, such as the National Rose and Chrysanthemum Societies, I have seen first prize exhibits in these decorative classes which, could they have been removed and placed in some well-appointed dining-room, would look perfectly incongruous, both as regards the quality and diversity of material used, and also the receptacles in which they were arranged. Who, for example, would tolerate the now very antiquated epergne in which a mixture of three or four varieties of flowers are often arranged at shows, and draped with various trailing subjects, as a centre-piece to their dinner table? Such schemes may appear very pleasing to the uninitiated, but surely they would not appeal to those of artistic tastes. Such, at least, is my opinion, and I speak from a fairly wide experience, gained ofttimes through the sacrifice of many hours of leisure. My object in writing is because I feel that horticultural societies might well endeavour to encourage something more practical and of more educational value in their decorative classes; a point, by the way, that I have often insisted on in committee. It would be interesting and instructive to know the views of other practical men on this subject. *Practical.*

Aconitum Fischeri.—In my note on autumnal flowers (page 248) I write in error of Aconitum Wilsonii, whereas the species I meant to indicate was A. Fischeri, Reichb. The two species flower simultaneously, but the latter is more profuse in bloom. *Herbert Maxwell, Monreith.*

Holland Park Hall Show.—I have not been surprised to read the correspondence from exhibitors and intending exhibitors at the autumn fruit and vegetable exhibition of the R.H.S. on October 2, 3 and 4. I agree with Mr. Carpenter (p. 266) when he states that he is voicing the opinions of many, in thanking you for your article in *Gard. Chron.*, October 13, which has resulted in letters from several well-known exhibitors. I had intended exhibiting in at least five Grape classes had it not been for the earlier closing of the date for entries. I wrote to the Secretary of the R.H.S. on September 15 for a schedule; instead of a schedule I received a postcard, stating that entries for the autumn fruit show closed on August 30. Many will, I am sure, agree with me that to close the entries five weeks before the date of exhibition is ridiculous. Had I entered the collection of nine dishes of fruit on August 30 I should have been obliged to have cancelled my entry, owing to the unfavourable weather we experienced during September for the keeping and finishing of my fruit. I have heard from several exhibitors of former years who expressed disgust and surprise at the early closing of the entries. The disadvantages and inconveniences of the Holland Park Hall are not a few, and unless a more suitable hall can be found for the holding of the R.H.S. general autumn exhibition, I am certain exhibitors and visitors would prefer an exhibition of autumn fruits, such as we have had in former years, at the R.H.S. Hall, Vincent Square. *J. Lock, Oatlands Gardens, Weybridge.*

SOCIETIES.

SOCIETE NATIONALE D'HORTICULTURE DE FRANCE.

The autumn exhibition of the above Society was held from October 25 to November 4, in the usual place, namely at Cour la Reine, which, by the way, is now scarcely large enough to accommodate the numerous visitors. The exhibition was favoured by fine weather, and was a great success.

The Grand Prix d'Honneur, given by the President of the Republic, was awarded to MM. Salomon, of Thomery, for their exhibit of Grapes; it would be difficult to imagine anything finer than the fruits shown by this firm.

Novelties.

Numerous Certificates of Merit were awarded for new Chrysanthemums—no fewer than forty-five, of which nineteen were won by MM. Vilmorin, and ten by Mme. Martin, of Champigny. Some varieties which should prove of value are Le Gévaudan, pink; La Limagne, white; Le Sénonais, gold and brown (all these from MM. Vilmorin, Andrieux et Cie.); Chrysanthémiste Sadarnac, pink; Gaston Clément, brown with gold reverse; Ministre Chéron, reddish brown (these from Mme. Martin); Tapis Violet and Phare, pink with large petals, known as "market varieties," raised by M. Morin, of La Rochelle; Mme. Jeanne Serre, white shaded with pink (M. Féron); Petit Paul, a pale pink sport from Undaunted (M Laveau); and Yvette Lochot, pure white (M. Lochot).

Three Certificates of Merit were awarded for Carnations, all to MM. Idot et Durieux, of Croissy sur Seine, for the varieties Mme. Albert Henriot (bright pink), Mme. Paul Lécolier (bright salmon), and Sénégalais (garnet red). A Certificate of Merit was also awarded to MM. Vacherot and Lecoufle for Nephrolepis Maurice Vacherot, a graceful Fern with fronds delicately curled.

MM. Lize, of Nantes, showed a new Aralia, A. Lizei, with handsome foliage, recalling that of a large-leaved Ivy.

Chrysanthemums.

MM. Vilmorin, Andrieux et Cie., of Paris, had the largest non-competitive exhibit of Chrysanthemums (see Fig. 109), occupying all the central portion of the large tent, and brightened by flower-covered arches. On each side were groups of pot-plants in a number of varieties, some in ordinary form, some trained as pyramids, and some (single-flowering kinds) cones. In the centre were grouped the unnamed novelties presented for award Among the varieties best represented in the exhibit were Petite Elise, white; La Beauce, yellow, Le Médoc, pink; G. Laplace, salmon pink; Admiral Beatty, pinkish white, and Louisa Pockett.

The firm of M. Truffaut, of Versailles, arranged half a dozen immense conical erections, over 12 feet high, each composed of a considerable number of plants of the same variety, for example, Ami Paul Labbé, russet; R. C. Pulling, yellow; Captain Fox, red with russet centre; Mrs. Gilbert Drabble, white; and Undaunted, pink with paler reverse; the whole was composed of flowers of excellent cultivation, and very neatly set up.

The Horticultural College of the City of Paris (Professor M. Pinelle) showed a very fine set, some cultivated in the ordinary way, and some disbudded, including La Beauce; Sharpe's Beauty, russet; Pluie d'Argent, a fine white border variety; and Colonel Linel, reddish brown with a yellow centre. From the firm of Ferard, of Paris, came a large and very fine group of single varieties, grouped by colour in well-arranged masses, and including Caennais, pink; Orléanais, yellow; Poitevin, pale pink; and Robert Laumonnier, garnet red.

M. Labbe, of Thiberville (Eure), sent cut flowers of very large size, among which were James Stredwick, yellowish pink; Baby Guy, pure white; and General Castelnau, pink M. Lochot, of Pierrefitte, had Mrs. G. Monro, deep red, and Majestic and Rayon d'Or, both yellow. M. Feron, of Garches, exhibited some enormous blooms of R. C. Pulling, Ami Paul Labbé, Mrs. Drabble, Edith Cavell, and others; while MM. Leveque sent from their nurseries at Ivry a fine lot of plants in pots, comprising René Piot, white; Emile Rodrique, white with greenish centre; and Président Poincaré, pinkish white. MM. Nonin, Châtillon sous Bagneux, showed Président Millerand, brown, with paler reverse; Daily Mail, yellow; and W. Turner, white.

Sundry Plants and Flowers.

As there had been no frost to spoil them, MM. Cayeux et Le Clerc were able to show a very fine group of cut Dahlias, comprising the best up-to-date varieties; the new decorative kinds, with rigid stems showing well above the foliage, included Mme. Victor Cayeux, bronzed yellow; Mme. Sans-Gêne, pink; Augustinus, pink; Florise, yellow; Cav Clerc, bronzed yellow; Marc Aureau, a fine pink; and the Cactus varieties Ibis, orange, and Colibri, pink tipped with white.

MM. Nonin, of Châtillon sous Bagneux, also showed a fine collection of Dahlias, including Mme. Diesny, lilac-pink; Porthos, mauve-violet; Orange Bowen, brownish yellow; and Gaston Clément, bright red (a Cactus variety).

There were several interesting groups of Carnations, notably those of MM. Idot et Durieux, of Croissy sur Seine, who showed Souvenir du Capitaine Thuilleaux, red carmine; Verdun, garnet; Mme. Alexis Idot, salmon pink; of M. Lochot, Pierrefitte, who had Alsace and Président Viger, both pink; and of MM. Vacherot et Lecoufle, of Boissy St. Léger, who showed Marie Lecoufle, mauve-pink; Marie-Louise, pure white, and M. Jeannet, deep garnet red.

M. Aubert-Maille, of Tours, had a fine exhibit of Cyclamens; and the usual specialists in tuberous Begonias, namely, MM. Billard, du Vésinet, and Vallerand, of Taverny, exhibited excellent Begonias in brilliant colours.

There were a number of first-class exhibits of Roses, notably by MM. Leveque et Fils, of Ivry; M. Honore Defresne, of Vitry; and MM. Nonin, of Châtillon sous Bagneux, the last showing the beautiful new **Rose America.**

Greenhouse foliage plants were excellently shown by M. Cuny, head gardener at the Luxembourg Gardens, in Paris; his group comprised beautifully cultivated specimens of Cyclanthera bipartita, Philodendron Soumi, Sphoerogyne, Cinnamonum, Anthurium cristallinum, Dracaena Rotheana, Heliconia illustris, Codiaeum B. Comte, and C. aurea Regeli.

M. Weiss, of St. Cloud, arranged a pretty "Japanese" scene, in which Thuya obtusa, fruiting Skimmia, Picea excelsa pendula, and other suitable plants were used effectively; and M. E. Thiebaut, of Paris, had made a pleasing little rock garden.

As in former years, the Orchid Committee of the Society had combined, and showed a collective exhibit, in which were particularly noticeable Brasso-Cattleya l'Yser, with pink labellum finely fimbriate (Maron); B.-C. Souvenir de Maneyrol, deep pink labellum (Maron); B.-C. Mirabeau, deep pink, with paler divisions (Maron); Cattleya Nankin, yellow, with pink-bordered labellum (Maron); C. Fabia × aurea, a beautiful deep red (Dr. Gratiot); and Brasso-Cattleya Marguerite Fournier × Austerlitz, with deep red labellum.

The Julien Potin Cup for the finest Orchid shown was awarded to Laelio-Cattleya Carmencita var. Saint James (garnet-red labellum, chamois-yellow segments) shown by M. Perrin, of Clamart. M. Bert, of Bois-colombes, exhibited the fine Cattleya Marie Bert, with pink labellum edged with white and white petals. There was an excellent display of Cypripediums from the houses of the Luxembourg gardens, including C. Abel Chatenay, C. G. Buttel, and C. Mme. Albert Février.

Fruits and Vegetables.

The exhibits of fruits were numerous and very good As already mentioned, the Grand Prix d'Honneur was won by the firm of Salomon for Grapes, exhibit including such

Digitized by Google

varieties as Alphonse Lavallée, Alicante, Muscat of Alexandria, Angelino, and Cornichon Blanc.

Other important exhibits were those of MM. CROUX ET FILS, of Châtenay; MM. NOMBLOT, of Bourg-la-Reine; MM. MOSER, of Versailles; and MM. CHAUFFOUR, also of Versailles. Among the trade exhibits of commercial varieties, perhaps the most important was that of the MONTREUIL HORTICULTURAL SOCIETY, including enormous fruits of Pears Doyenné du Comice, Beurré Clairgeau, Beurré Diel, Passe-Crassane, Olivier de Serres, and Doyenné d'Hiver; Apples Calville Blanc; and Apples Api, Belle de Pontoise and Grand Alexandre decorated with various inscriptions.

The students of the Arboricultural Course at the Luxembourg Gardens sent an interesting exhibit, and so did the growers' association at Thomery, who showed a fine lot of Grapes Chasselas de Fontainebleau. M. DURAND, of Bagnolet, showed dessert fruits, including Apple Api d'été, Pear Doyenné du Comice, and Peach Salway; and M. GERMAIN, formerly an actor at the Palais Royal Theatre, had some enormous fruits, notably two Pears of the variety Belle Angevine, from the same cluster, which weighed together over eight pounds.

Vegetables were chiefly represented by an important group from the firm of VILMORIN, which was very ornamental in the diversity and beauty of the products composing it. There were baskets of Cauliflowers, diamond-shaped displays of Chicory, and Savoy Cabbages bordered with Chili, Pimento, etc., in addition to several Cucurbits—Gourds of Touraine, Mammoth Pumpkins, and Vegetable Marrows, one of the last measuring more than a yard and a half in length.

MM. TRUFFAUT, of Versailles, also showed a fine collection of vegetables, decorated with Chili Beets and fruits of Physalis Franchetii, and including some giant Potatos. The HORTICULTURAL COLLEGE at Igny showed a varied collection of very fine vegetables, notably the pink Malaga Batata; and M. PICARD, of Courville (Eure et Loire), had an interesting display of Colocynths of highly ornamental (spotted, warted, and striped) varieties.

Trained fruit trees, a Parisian speciality, were well to the fore. MM. NOMBLOT, of Bourg la Reine; MM. CROUX, of Châtenay; MM. MOSER, of Versailles; and MM. CHAUFFOUR, also of Versailles; all showed excellently trained trees in every variety of shape and form. Among the exhibits of ornamental trees and shrubs, the most notable were those of M. LECOLIER, of La Celle Saint-Cloud; M. THUILLEAUX, also of La Celle Saint-Cloud; and M. MARTIN-LECOINTE, of Louveciennes; some fine specimens of Cupressus Lawsoniana Gloire de Boskoop, Picea Kosteri, Cotoneaster Franchetii, Abies Pinsapo pendula, Euonymus radicans Silver Gem, Ilex Aquifolium marginata alba, and Taxus baccata elegantissima were noted. *A. M.*

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE monthly meeting of this society was held in the R.H.S. Hall on Monday, November 12, Mr. T. R. Butler presiding. Six new members were elected.

Sir Wm. Lawrence, Bt., notified his intention of becoming an honorary life member, while also Messrs. John Russell, Ltd., and Mr. H. G. Dick have become honorary members. Two members withdrew interest from their deposit accounts amounting to £4 13s. 7d., and four members over the age of 70 years withdrew £140, which still leaves one member with over £100 to his credit. The sum of £27 12s. 11d. was passed for payment to the nominee of one deceased member.

Dental and surgical grants were made to four members, amounting to £10 3s. 3d., and the applications of eight other members were discussed. The sick pay for the month on the ordinary side amounted to £57 18s. 11d., on the State section to £51 9s. 6d., and maternity claims to £12. The Treasurer stated he had a balance in hand of £1,072 15s. 2d.

ROYAL HORTICULTURAL.

NOVEMBER 13.—On the occasion of the meeting held at Vincent Square, Westminster, on the above date, there was a bright exhibition, but the hall was not so well filled with exhibits as on recent occasions. Chrysanthemums, Carnations, Orchids, dwarf Conifers, Violets, Grapes and Apples were the principal features. Novelties were few in number and the awards by the Floral Committee were made exclusively to florists' varieties of the Chrysanthemum.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Sir F. W. Moore, Messrs. Jas. O'Brien (Hon. Secretary), Gurney Wilson (Assistant Secretary), R. Brooman White, C. J. Lucas, Arthur Dye, F. K. Sander, H. H. Smith, H. G. Alexander, C. H. Curtis, H. T. Pitt, W. J. Kaye, Richard G. Thwaites, J. Wilson Potter, and Stuart H. Low.

A Silver-Gilt Lindley Medal was awarded to Odontoglossum Purple Emperor (The Czar × Dusky Monarch), from H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood). The plant shown was the original specimen which had previously secured a First-Class Certificate, but which a large majority of the Committee considered such a superb hybrid as to be worthy of an exceptional award. The flowers are of perfect shape and of the largest type of Odontoglossum. They are coloured dark velvety purple with a narrow but distinct fimbriated white margin, the front of the labellum being white.

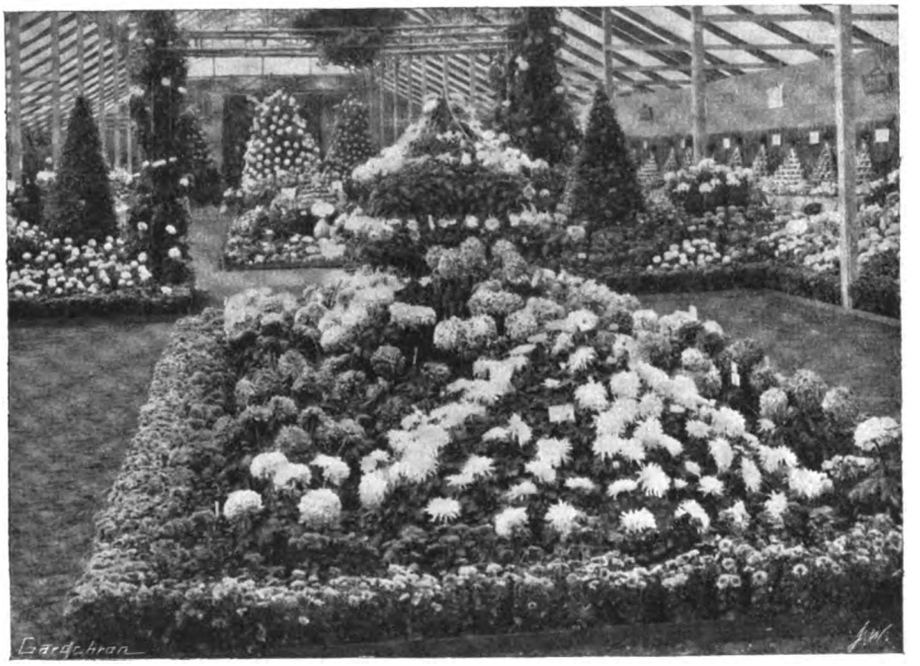

FIG. 109.—VIEW IN THE PARIS CHRYSANTHEMUM EXHIBITION.

FIRST-CLASS CERTIFICATE.

Odontoglossum Ithone (*Aglaon* × *Dusky Monarch*), from Messrs. CHARLESWORTH AND CO., LTD., Haywards Heath. A fine cross beyond compare in its section. The plant bore a grand spike of eleven flowers of perfect shape, the greater part of the surface being dark claret-red with white margins, and two oblong, window-like silver blotches in each segment; an unusual arrangement of colour.

GROUPS.

Messrs. STUART LOW AND CO., Bush Hill Park, and Jarvisbrook, Sussex, were awarded a Silver Banksian Medal for a very interesting group containing a good proportion of novelties, one of the best of which was Brasso-Cattleya Rosy Glow (C. Leda × B.-C. Mrs. J. Leemann), a grand, rosy-mauve flower with glowing yellow disc to the broad-fringed lip. Cattleya Annette (chocoensis alba × Warscewiczii var. F. M. Beyrodt) was shown in several fine white forms with Tyrian purple lip, and other white forms were included. Sophro-Cattleya Sir Mervyn Buller (C. Empress Frederick × S.-C. Wellesleyae) has charming salmon-rose flowers with ruby-red lip; and among the Brasso-Cattleyas were several distinct forms, whilst in the yellow Laelio-Cattleya section, which was well represented, L.-C. Golden Oriole Low's variety was prominent. A specimen of Dendrobium Phalaenopsis Schröderianum had many graceful sprays of flowers.

Messrs. COWAN AND CO., Southgate, received a Silver Banksian Medal for a very compact group in which Cypripediums were the main feature. The novelties were Cypripedium Charlestonii (Charlesworthii × Lord Ossulston), a very distinct and pretty flower, and C. Clytemnestra (Aeson giganteum × Gaston Bultel), a hybrid well worthy of its good parents. Oncidium flexuosum with its pretty yellow sprays was at the back of the group with a selection of Brasso-Cattleyas, for which the firm is noted, good Laelio-Cattleyas, the new L.-C. Nanon, the favourite L.-C. Dodona in two very dissimilar forms; and yellow Cattleyas, among which was one of the best C. Venus. The white and purple C. Hassallii alba was also well shown.

OTHER EXHIBITS.

Messrs. J. AND A. MCBEAN, Cooksbridge, staged a collection in which their best plant was L.-C. Profusion var. Majestic, a fine form of that which secured an Award of Merit at the last meeting. There were also the new white Cattleya Warscewiczii Fairy Queen, which has a very pretty rose-tinted lip; the white Cattleya Brenda, Miltonioda Hilda and other good hybrids.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, sent their new Laelio-Cattleya Ensign (L.-C. Orion × C. Fabia), a well-formed rosy-mauve flower with a purple band on the petals, and a ruby-red lip.

Messrs. SANDERS, St. Albans, showed a magnificent form of Brasso-Cattleya Boadicea var. Verulam (B.-C. Digbyano-Schröderae × C. Warscewiczii Sanderiana), with two fine rose-pink flowers with soft yellow disc to the lip.

Messrs. CHARLESWORTH AND CO. showed a fine form of their Vuylstekeara Edna (Miltonioda Harwoodii × Odontioda Charlesworthii) with a heavy spray of red flowers.

Floral Committee.

Present: Mr. H. B. May (in the chair), Sir W. Lawrence, and Messrs. W. J. Bean, Arthur Turner, H. J. Jones, J. Jennings, C. R. Fielder, D. B. Crane, W. B. Gingell, Chas. E. Pearson, E. A. Bowles, G. Reuthe, John Heal, George Harrow, Jas. Hudson, W. B. Cranfield, H. V. Warrender, Clarence Elliott, Reginald Cory, C.

Digitized by Google

Williams, W. Howe, J. F. McLeod, Montague C. Allwood, J. B. Riding, and W. Baker.

AWARDS OF MERIT.

Chrysanthemum Mrs. J. Palmer.—This is a very large pure white single variety with slightly drooping tips to the pointed florets.

Chrysanthemum Norman.—A handsome rich golden yellow single variety of good size and fine form. The florets are broad, but the "eye" is rather prominent.

Chrysanthemum Miss Joyce Moore.—A bright crimson-scarlet single variety belonging to the large-flowered section. The colour is particularly rich and bright.

Chrysanthemum Pink Beauty.—Yet another large-flowered single variety, in which the colour is deep pink, with a white zone round the eye. These four varieties were shown by Mr. G. CARPENTER, West Hall Gardens, Byfleet.

Chrysanthemum Radiant. — A reflexing Japanese variety, with broad florets that make up a compact head. The colour is golden bronze. Shown by Mr. H. J. JONES.

GROUPS.

Chrysanthemums were distinctly the most important floral feature in the hall. Messrs. W. WELLS AND CO. set up a very handsome and imposing collection. Their tall stands contained a large number of exhibition Japanese varieties of great size and very high quality. The principal varieties were Mrs. Gilbert Drabble, white; Mrs. F. J. Fleming, Mrs. R. C. Pulling and Wm. Rigby, yellow; Mrs. Harold Wells, crimson amaranth; Majestic, golden amber; and Louisa Pockett, white, tinted with mauve. Amongst the smaller Japanese varieties were White Cheer, Golden Butterfly and Primrose. Besides these Messrs. Wells and Co. displayed a goodly selection of the best singles, and several very decorative Anemone-flowered varieties (Silver-Gilt Flora Medal).

In another part of the hall Messrs. KEITH LUXFORD AND CO. arranged a very attractive collection of Chrysanthemums. Their exhibition Japanese varieties included Sulphur Queen, Majestic, Dr. J. M. Inglis, purple amaranth with golden reverse; and Roma Baylis, blush pink. Single-flowered varieties were also freely shown and in equally good quality. These included Florizel, dull cardinal; Caledonia, mauve; Nona, white; and Sussex, yellow. A couple of vases of mixed Pompons contained flowers of the tiniest size, yet perfect of form, and charming colouring (Silver Flora Medal).

Mr. F. G. WOOD included some decorative vases of such Chrysanthemums as Golden Marvel and Emperor, with his miniature rock gardens (Bronze Banksian Medal), and Messrs. BAKERS, LTD., had vases of similar types in association with shrubby Veronicas, Erigerons and Helenium cupreum Crimson Beauty.

A very beautiful collection of Nerines was staged by Messrs. BARR AND SONS. They showed several distinct types of this valuable cool greenhouse bulb, and of them all, N. Aurora, which may be described as a rich pink N. Bowdenii, was decidedly the most prominent. This was the largest spike of all, yet very graceful and delicately beautiful. N. Albatross, N. Ariel and N. Ariadne of N. undulata type embraced some lovely shades of colour. Of these the larger-flowered type N. Lady Acland, rose; N. Nancy, deep pink; N. Mrs. Thursby, deep salmon; N. Red Hussar; and N. Mrs. Molesworth, rose cerise, were of great value (Silver-Gilt Banksian Medal). Many plants of Nerine were also staged by Mr. G. REUTHE, and although they were not of such merit as the foregoing, there were many desirable varieties amongst them. N. Prince of Orange, N. flexuosa alba, N. flexuosa major, N. Plantii laxifolia and several N. undulata varieties were very graceful. Mr. REUTHE also set up a small collection of alpines in pots (Silver Banksian Medal).

Carnations of considerable merit were shown, and these were chiefly of the perpetual-flowering type, though Messrs. ALLWOOD BROS. included some very decorative vases of their Dianthus Allwoodii. Amongst their larger varieties were Laddie, George Allwood and Mrs. Walter Hemus, pink shades; Maine and Sunshine, yellow; and the fancy, Chintz (Silver Flora Medal).

In the centre of a group of Carnations set up by Messrs. STUART LOW AND CO. were several vases of the beautiful pink variety, Hon. Nita Weir, Eileen Low, of similar colouring; Brilliant, Red Ensign and Sir Mackay Edgar, crimson shades, were also especially good (Silver Banksian Medal). Mr. C. ENGELMANN included such valuable sorts as Donald, Tarzan and Topsy, crimson shades; White Enchantress and White Wonder in his display of Carnations (Bronze Flora Medal). Some very good plants of Primula obconica in three or four varieties of distinct colours were shown by Mr. E. H. CAUSER, who also staged a decorative batch of greenhouse Cyclamen with Ferns in variety (Silver Flora Medal).

Violets of especial merit were contributed by Miss E. HEATHCOTE. These were named "The Eastfield Princess of Wales," and were characterised by exceptional length of stalk, large size of flower, deep colour and delightful fragrance (Bronze Flora Medal). Mr. J. J. KETTLE had a good variety of Violets, both singles and doubles, and also showed vases of both types in pale blue colour (Silver Banksian Medal). Mrs. LUCAS also contributed Violets.

For the most part the hardy plant exhibitors staged excellent little Conifers suitable for planting in the rock garden. Mr. G. G. WHITELEGG had a good variety of Junipers, Cupressus, Pines and Firs, with a pretty group of Primula capitata (Silver Banksian Medal).

The ORPINGTON NURSERIES CO. staged similar Conifers (Silver Banksian Medal), Mr. J. KLINKERT had well-trained topiary specimens (Bronze Flora Medal), and the Misses HOPKINS had an interesting little collection of hardy border plants.

Just inside the entrance Messrs. L. R. RUSSELL, LTD., had an attractive collection of hardy shrubs. Besides several well-coloured "Silver" Ivies there were Cotoneaster pannosa and Skimmia japonica bearing brightly coloured berries, standards of Euonymus latafolius alba, Ilex Pernevi and Corokea virgata (Silver Banksian Medal).

Mr. ELISHA J. HICKS again showed vases of the splendid pink H.T. Rose America.

Fruit and Vegetable Committee.

Present: Messrs. Jos. Cheal (in the chair), W. G. Lobjoit, H. S. Rivers, Geo. F. Tinley, P. D. Tuckett, W. F. Giles, T. Pateman, A. Bullock, E. Neal, F. Jordan, N. F. Barnes, Ed. Beckett, G. Reynolds, H. Markham, W. H. Divers, E. A. Bunyard, H. N. Rawes and J. Wilson.

Three or four seedling Apples were sent for award, but none was considered of sufficient merit. The most promising was a seedling named C. B. Stiby sent by Mr. T. MACPHAIL, County Education Office, High West Street, Dorchester. The samples shown were of uneven size, some small, others large; the largest fruit was very handsome, with pale yellow skin prettily flushed with red on the sunny side. The variety is said to keep until June, and the Committee recommended that it should be seen again in that month. The variety Lord Lambourne, which Messrs. LAXTON BROS. has shown on one or two occasions in the competition for the Bunyard Cup offered for the best flavoured Apple, was recommended for inclusion in the trial of commercial varieties at Wisley.

Messrs. J. CHEAL AND SONS showed two old Sussex Apples named Nannie and Forge, both of attractive appearance and of a size suitable for dessert purposes. It was stated that a tree of Nannie variety in Messrs. Cheal's nursery produced a crop of thirteen bushels this season. Hogg describes it as a dessert Apple of excellent quality, and when in perfection a first-rate fruit. Forge is stated to be a cottager's Apple *par excellence* in that part of Sussex which is conterminous to Surrey and Kent. It originated at Forge Farm, near one of the old forges in the iron districts of Sussex, near Crawley.

A Seedling Potato with red skin, of the Mr. Bresse type, with somewhat deep eyes, was shown by Mr. J. BUCHANAN, The Gardens, Gargunnock, Stirlingshire. Mr. Buchanan stated that the variety was earlier than Puritan and immune to wart disease. The Committee recommended the variety to be tried at Ormskirk.

GROUPS.

Some excellent bunches of Muscat of Alexandria Grapes and of Cooper's Black variety, were shown by the Hon. VICARY GIBBS (gr. Mr. E. Beckett). There were eighteen bunches of Muscat of Alexandria, and the largest weighed close on four pounds. All the bunches were shapely and the berries large and well finished. They were, in the opinion of many, some of the best Grapes exhibited this season. There were six bunches of Cooper's Black, and these were arranged, three at either end, for the Grapes were displayed on attractive stands, like miniature easels, in a single row (Gold Hogg Medal).

Messrs. J. CHEAL AND SONS showed a very excellent exhibit of Apples, comprising in all sixty-six distinct varieties. The exhibit was tastefully decorated with sprays of berried shrubs, and autumn-tinted foliage. Conspicuous place was given to the variety Crawley Beauty, fruits of which were exceptionally good this year. One of the showiest varieties was Paroquet, a magnificently coloured Apple and of pleasing appearance generally. Other sorts worthy of mention are Cox's Orange Pippin, Herring's Pippin, Gascoyne's Seedling, Fearn's Pippin, Lord Derby, American Mother, Duke of Devonshire, London Pippin, Sandringham and King of Tompkin's County (Silver Hogg Medal).

Trial of Dwarf Tropaeolums.

The following awards have been made by the Royal Horticultural Society to Dwarf Tropaeolums after trial at Wisley.

AWARD OF MERIT.

Fireball sent by Messrs. NUTTING AND SONS, LTD., London.

HIGHLY COMMENDED.

Empress of India, sent by Messrs. J. CARTER AND CO., Raynes Park.

NATIONAL CHRYSANTHEMUM.

AT the meeting of the above Society's Floral Committee, held at the Royal Horticultural Hall, during the afternoon of November 12, fifty new Chrysanthemums were submitted for consideration, and so high was the general quality of the varieties shown that no fewer than sixteen First-Class Certificates and four Commendations were awarded, the successful varieties being as follow:—

FIRST-CLASS CERTIFICATES.

Pink Beauty (V.1.A.).—A large, single variety of graceful form; the colour is pink, with a white zone around the eye.

Mrs. J. Palmer (V.1.A.).—A pure white, large-flowered single variety with numerous and substantial florets.

Miss Joyce Moore (V.1.A.).—A large-flowered single variety, but not of such large size as some others exhibited. It is of good form and brilliant crimson-scarlet colouring, being one of the most vividly coloured single varieties we have yet seen.

Norman (V.1.A.).—In this variety the florets are broad, well arranged, and form a very attractive flower, which is of deep gold colour.

Miss Golby (V. 1.A.).—A large-flowered bright chestnut-red, single variety.

Mr. P. Matcham (II. 1.B.).—An attractive medium-sized Japanese variety of graceful form and with chestnut-bronze colouring.

Miss A. Wisbey (V.1.A.).—In this large-flowered single variety the florets are broad and regularly disposed. The colour is deep gold lightly tinted with bronze. The foregoing seven varieties were exhibited by Mr. G. CARPENTER, West Hall Gardens, Byfleet.

Isolde (II. 1.B.).—A pleasing Japanese variety of useful decorative size and light buff colouring.

Heloise (V. 3).—A dainty and altogether charming Anemone-single variety of medium size and exquisite salmon-rose colouring. It appears to be very free-flowering, and should provide a colour which is often required by florists. These two varieties were exhibited by Messrs. CRAGG, HARRISON AND CRAGG, Heston.

Digitized by Google

Amber Queen (II. 1.B.).—A medium-sized Japanese variety of the decorative type, with slightly drooping and moderately broad florets. The colour is golden fawn or apricot. Shown by Mr. H. POULTON, Pippbrook, Dorking.

Mrs. Harold Wells (II. 1.A.).—A very large, incurved Japanese variety of full exhibition size. The broad and pointed florets are ivory-white, but the whole flower has a tint of very pale green.

Duchess of York (II. 1.A.).—A large Japanese variety with reflexing and drooping florets. The colour is a rich purplish-crimson, and the flowers have a velvety appearance. These two varieties were shown by Mr. H. SHOESMITH, Woking.

Bernard Hicks (V.1.A.).—A fine, large-flowered single variety of deep rich crimson colouring. The flowers are of good form and carried on excellent stems. Shown by Mr. T. STEVENSON, Cowley.

Nona (V.1.A.).—A particularly fine, large-flowered, single variety with very broad, pure white florets which make up an attractive flower of excellent form.

Mr. A. Robertson (V. 1.A.).—A very large single variety, a trifle loose in form, but of fine deep pink colour.

Sulphur Queen (II. 1.A.).—An immense incurved Japanese variety of largest exhibition size and light sulphur yellow colour. These three varieties were shown by Messrs. KEITH, LUXFORD AND CO., Harlow.

COMMENDATIONS.

Flavia (V.2.A.).—A very pleasing free-flowering single variety, with slightly cupped flowers with broad florets and of a pleasing bronzy-orange shade of colour. Shown by Messrs. CRAGG, HARRISON AND CRAGG.

Sunburst (II. 1.B.).—A bright and attractive, medium-sized Japanese variety, of considerable decorative value, and the colour, as officially given, is salmon terra-cotta. This variety was placed before the Committee under the name of Crusader, but as that name is already in use, Sunburst was substituted. Shown by Mr. H. SHOESMITH.

Red Rover (II. 1.B.).—Another attractive Japanese variety belonging to what is popularly known as the decorative section. It has firm florets, good form, and is of bright chestnut-red colour. Shown by Mr. H. J. JONES, Lewisham.

Mrs. F. J. Yarrow (V. 1.A.).—An effective, large-flowered single variety of brilliant chestnut-crimson colouring, but its stems are rather too thick, and its foliage over large to satisfy the modern requirements for a decorative single Chrysanthemum. Shown by Mr. A. ROBERTSON, St. John's Wood.

SHEFFIELD CHRYSANTHEMUM.

NOVEMBER 9, 10.—The Drill Hall, Edmund Road, Sheffield, is a spacious, unheated building, and at ordinary times uninviting. But on the above dates, when Chrysanthemums were to be seen at their best, it presented a feast of glorious colour, for nowhere is interest greater in these autumn flowers than in and around the city of steel

Unfortunately the open classes attracted few entries, which in view of their numbers at previous shows may perhaps be accounted for by the unfavourable season, for the prize money in some cases has been increased, and in no single instance has it been reduced. Disappointment was freely expressed at the absence of any entry in the decorated fruit-table class for which £5 is the first prize, and vegetable growers especially missed the entries from the south, for these have always been a great attraction.

Fortunately, trade displays were more in evidence than we have seen them since the war, and very fine were the gold medal exhibits of all types of Chrysanthemums set up by Mr. H. Woolman, Shirley, Birmingham; Messrs. W. Artindale and Sons, Sheffield; Messrs. Brock Bray, Ltd., Sheffield; and Messrs. Seagrave and Sons, Sheffield; and the Carnations from Mr. C. Engelmann, Saffron Walden; Cyclamen from Messrs. W. Artindale and Sons, and the monster Onions shown by Messrs. Dickson and Robinson, Manchester, which were also awarded gold medals. Occupying one side of the hall, the Sheffield Wholesale Traders combined to set up an interesting display of all kinds of English and foreign fruit, while the English Apples from Messrs. Lowe and Shawyer were perhaps the finest ever seen in bulk in Sheffield and commanded a ready sale.

The principal open class was for 8 vases of Japanese Chrysanthemums, in 8 varieties, 3 blooms in a vase, for which £9 was the first prize; this brought only two entries, and Mr. H. WOOLMAN, Shirley, was awarded first prize, his blooms being amongst the best ever seen in Sheffield. Some of his best varieties were Ryecroft Triumph, a fine rich crimson showing no reverse; Queen Mary, Victory, Mrs. E. Tickle, Majestic, Mrs. A. Davis, and Mrs. B. Carpenter. G. CHAMBERS, Esq., Manor House, Pilsley (gr., Mr. C. Bowyers), was a creditable second prize-winner with Queen Mary, Mrs. A. Davis, and Mrs. G. Monro amongst his best blooms. No entries were forthcoming in the classes for 3 red or pink Japanese blooms, and none for 3 white flowers. Mr. W. E. HYDE, however, was awarded a second prize in the class for a single vase of yellow Japanese blooms. Incurved flowers were well shown by local amateurs, and as there was no competition from a distance, Mr. C. FLETCHER, Mr. A. FLETCHER, and G. CHAMBERS, Esq., easily led in the order given. Substantial prizes were offered in the class for 6 vases of decorative varieties; 1st, Mr. WM. FLETCHER; 2nd, Mr. W. E. HYDE.

The class for a basket of Chrysanthemums arranged for effect provided keen competition amongst three exhibitors; 1st, Mr. W. SMITH; 2nd, Mr. E. P. AITKEN; 3rd, R. DYSON, Esq., Fairfield, Rotherham. A class that always attracts attention is the one for a display of single Chrysanthemums to occupy a table space of 20 ft. by 4 ft. Following up a long series of successes, Mr. H. WOOLMAN again secured first prize. His was a wonderful effort, embracing all the leading varieties in the best possible condition, noteworthy amongst them being Coronet, Bronze Molly, Mensa, Catriona, Mrs. W. Smith, a fine white Bertha Fairs, Sweet Auburn, Phyllis Cooper, and Absolute, probably the most fascinating single introduced. Mr. W. E. HYDE won second place, and for a local effort his was a really good one. A new class was this year provided by the Bridgewater Nurseries, Ltd., for 9 vases of large-flowered singles, 6 blooms in a vase, open to all except trade growers. Two competitors, both local, contested for a good prize, and the winner, R. DYSON, Esq. (gr., Mr. H. J. Nicholson), put up an even set of well developed blooms. The best varieties were R. Godfrey, Esme Waters, Bronze Molly, Susan, and Sweet Auburn; 2nd, Mr. W. E. HYDE.

Interest in the district classes was centred round the one for 12 Japanese blooms, in not fewer than 6 varieties, to be staged on boards. Out of six entries Mr. C. FLETCHER was placed first with blooms which would not have been out of place in the open classes; 2nd, Mr. G. HOPKINSON; 3rd, Mr. A. FLETCHER. The class for 6 vases of singles also resulted in a good competition; 1st, Mr. G. HOPKINSON; 2nd, Mr. H. W. WALLERS; 3rd, Mr. E. HYDE.

The fruit classes were confined to local growers. R. DYSON, Esq. (gr., Mr. H. J. Nicholson), scored for white Grapes, and C. DIXON, Esq., Sandygate, Sheffield, won in the black Grape class. Apples and Pears were only of medium quality, and the entries poor. Local growers also had matters all to themselves in the vegetable classes. For a collection arranged for effect on a table space of 7 ft. by 4 ft., Mr. C. HYDE took first prize with a moderate collection. Competition was keener in the class provided by Messrs. Sutton and Sons, Reading, where Mr. E. HYDE again proved successful; 2nd, Mr. C. MAXFIELD; 3rd, Mr. C. H. WILFRED. Second and third prizes only were awarded in Messrs. Webb's class.

Altogether there were over 700 entries, and the amateurs' and cottagers' classes were well represented, the quality of both flowers and vegetables being distinctly good.

BRIGHTON AND SUSSEX HORTICULTURAL.

NOVEMBER 6 AND 7.—The enterprising and highly successful Brighton, Hove and Sussex Horticultural Society held its annual Chrysanthemum Show in the Dome and Corn Exchange on the above dates. The exhibition was one of the finest we have ever seen at Brighton, and it was so extensive that the Committee will have to seriously consider the advisability of securing a larger hall for the show and also a better-lighted one. The great platform under the Dome was splendidly decorated with Chrysanthemums, Palms and other flowering and foliage plants grown and arranged by Capt. B. H. Maclaren, the Superintendent of the Brighton Parks, who is also Vice-Chairman of the Society's Committee.

It was with regret we learned that Alderman J. Colman is retiring from the position of President, an office he has held with great distinction for a period of twenty-one years; we understand that A. Cooper Rawson, Esq., the local Member of Parliament, is to be his successor

FLOWERS AND PLANTS.

The Silver Bowl presented by the President, Alderman Jeremiah Colman, for the best two dozen Japanese blooms in not fewer than eighteen varieties, staged on boards, was won by F. E. RICHARDS, Esq. (gr. Mr. G. Tyler), Coombe Hall, East Grinstead, whose effective stand of fine flowers included capital specimens of A. F. Tofield, General Petain, Majestic, W. Turner, Princess Mary, Louisa Pockett, Lady Talbot, Mrs. A. Davis, and Helen Margerison; 2nd, C. CHANDLESS, Esq.; 3rd, Mr. W. H. APTED; five entries.

The best set of twelve Japanese blooms, distinct, on boards, came from F. E. RICHARDS, Esq., who had an even set in which the leading varieties were Majestic, F. S. Vallis, A. F. Tofield, Mrs. H. Tysoe, and Mrs. J. Gibson; 2nd, F. W. CHILVERS, Esq.; 3rd, Mr. W. H. APTED.

The best six Japanese blooms in one vase were shown by F. E. RICHARDS, Esq., who had big flowers of Thorpe Beauty, Mrs. G. A. Tickle, F. S. Vallis, Mrs. J. Balmer, Lady Talbot and Louisa Pockett; 2nd, Mrs. W. H. APTED, Broadwater, Worthing; 3rd, C. CHANDLESS, Esq. (gr. Mr. F. W. Chilvers), Sherrington Manor, Berwick Station.

There was a very keen competition in the class for three vases of Japanese blooms, five flowers of one variety in each vase. F. E. RICHARDS, Esq., won the premier award with huge examples of General Petain, Mrs. R. Luxford, and R. C. Pulling; 2nd, Mrs. J. T. KENWARD, Lewes; 3rd, Mr. W. H. APTED; there were six entries, and if the back row of vases had been raised a foot or so, the effect of the class would have been greatly improved. Mr. APTED led in the class for three vases of single varieties, and Mr. RICHARDS continued his successful career by winning first prize for six Japanese blooms in one large vase, with Mr. APTED second. There were three tables of single varieties, and these made an effective display the best flowers were shown by Mr. APTED, and his general arrangement was good; 2nd, Messrs. EASTWOOD AND SON, Downs Nurseries, Hassocks; 3rd, Mr. E. W. READ, Third Avenue, Brighton. Messrs. EASTWOOD led for a table of Carnation blooms with a capital display of popular sorts. Mr. J. C. REEVES, Puck's Croft, Rusper, was the most successful exhibitor in the class for a dozen single blooms arranged in a vase; 2nd. Mr. E. W. READ.

First prize for a basket of Chrysanthemums was awarded to Mrs. SWANN, Warninglid, Haywards Heath, for a design in yellow blooms; 2nd, Miss EASTWOOD, Hassocks; 3rd, Mrs. HALL, Southover Street, Brighton.

The judges awarded the Wm. Balchin Cup (value fifty guineas) to Mr. W. H. APTED, as first prize in the class for a circular group of Chrysanthemums. Mr. Apted certainly had the best flowers and arrangement, but each of the

Digitized by Google

three competing groups left much to be desired in the matter of elegant display; 2nd, W. H. Vokin, Esq. (gr. Mr. W. J. Scott), Beechwood, Withdean; 3rd, Mr. E. W. Read, Hove.

Fruits and Vegetables.

F. W. Chilvers, Esq., led in the class for two bunches of black Grapes with large clusters of Alicante; 2nd, Lt.-Col. P. R. Papillon (gr. Mr. E. Carpenter), Crowhurst Park, Battle, with very heavy bunches of the same variety; 3rd, Mr. W. H. Apted, with Gros Colmar.

Mr. A. H. Parsons, Lewes, showed the best basket of twelve culinary Apples—Lord Derby—and was also first prize winner in the class for four dishes of dessert Apples. The same exhibitor was similiarly successful in the class for four dishes of cooking Apples, distinct, with fine fruits of Lord Derby, Hawthornden, Pleasgood's Nonesuch and Newton Wonder. Mr. Parsons was also first prize winner in the class for two dishes of culinary Apples, winning with Gloria Mundi and Warner's King, but had to take second place to Capt. Almack (gr. Mr. R. W. Wheare), Danny Park, Hurstpierpoint, for two dishes of dessert Apples.

Messrs. Sutton's special prizes for a collection of six kinds of vegetables were won in order as named, by Lt.-Col. P. Papillon and Mr. J. C. Reeves.

Mr. J. Carley, Mallory House Gardens, Lewes, excelled in the class for a dozen Onions with very fine specimens of Ailsa Craig; 2nd, Capt. Almack; 3rd, Mr. A. H. Parsons. Magnificent Leeks were shown by Mr. G. Grove, Grantham Road, Brighton; Mr. M. Goocher and Mr. P. Prudden, who won prizes in order as named. Beets, Parsnips, Cauliflowers, Celery and Potatos were all extensively and well shown, but there were few Carrots.

In other classes for vegetables the principal prize winners were Mr. F. J. Bunney, Princess Crescent, Brighton; Sergeant Wheeler, Princes Road; and Lady Brand (gr. Mr. Down), Littledene, Lewes.

Non-Competitive Exhibits.

These were numerous and beautiful, the most notable displays being those of Chrysanthemums from Messrs. Keith Luxford and Co.; Mr. Jas. Box, who had Chrysanthemums, hardy flowers and fruits; Messrs. Balchin and Sons, a group of flowering and foliage plants and floral designs, including a lighthouse composed of white Chrysanthemums; the Barham Nurseries, fruit; Messrs. J. Cheal and Sons, flowers and fruits; Messrs. Sutton and Sons, a fine display of Potatos; Mr. H. C. Crule, Chrysanthemums; Mr. B. Pinney, Violets; Miss W. Walker, floral paintings; Messrs. G. Miles and Son, Chrysanthemums; Messrs. Tilley, vegetables; the Premier Seed Co., vegetables; and Mr. P. Warner Abbott, Chrysanthemums.

ROYAL OXFORDSHIRE CHRYSANTHEMUM.

This Society's show, held in the Town Hall, Oxford, on November 7 and 8, was, both in quality of exhibits and attendance, the best ever held. The exhibition was greatly enhanced by the exhibits of two fresh competitors, viz., Capt. R. B. Brassey, Collesbrooke Hall, Northampton, and Sir Mortimer Singer, Milton Hill, Steventon, Berkshire, whose gardeners, Mr. Quinn and Mr. Johnson, staged magnificent flowers and fruit. In the large hall were three groups of Chrysanthemums. The one shown by Mrs. G. H. Morrell, Headington Hill Hall, was the outstanding feature of the show. The blending of colours and the arrangement as a whole were perfect, and reflected great credit on her gardener, Mr. A. Gibson. His best blooms were: Louisa Pockett, R. C. Pulling, Queen Mary, Mrs. J. Gibson, General Petain, Majestic and Lloyd George. In addition, Mr. Gibson also staged an excellent group of Cattleya Bowringeana, Gesneras and Gloire de Lorraine Begonias, for which a Large Gold Medal was awarded. The group displayed by John Massey, Esq., contained a choice collection of blooms tastefully arranged by his gardener, Mr. A. Dawes (Gold Medal). Another fine group was by Messrs. Gee, Banbury Road, who made free use with good effect of some rich Singles intermixed with large blooms of Chrysanthemums (Gold Medal).

For nine varieties of Japanese Chrysanthemums in vases, in addition to a money prize, a Silver Challenge Cup was offered. This was the most keenly contested class in the show, and some handsome blooms were forthcoming. The First Prize was awarded to Capt. R. Brassey (gr. Mr. Quinn). His best blooms were Majestic, Rose Day, Princess Mary and W. Rigby. Sir Mortimer Singer (gr. Mr. Johnson) was a very close second. The best blooms in his exhibit were Majestic, W. Turner, Mrs. G. Monro, and Edith Cavell. Henry Balfour, Esq. (gr. Mr. Hewlett) was third. For twenty Japanese blooms, distinct, the first prize was awarded to Sir Mortimer Singer, with a grand vase of blooms, including Majestic, Lord Stewart of Wortley, F. Spring Watts and Louisa Pockett. Capt. R. B. Brassey was second, and H. Balfour, Esq., third. For twelve Japanese blooms, distinct, Mrs. Lessing won the first prize, and Mrs. Eccles the second (gr. Mr. Lawrence). Mrs. Lessing (gr. Mr. Down) excelled in the class for six blooms of a white variety—very fine specimens of Louisa Pockett. Sir Mortimer Singer gained first prize for six yellow blooms with splendid specimens of Mrs. R. C. Pulling. Second Mrs. Eccles, and third H. Balfour, Esq. For six blooms of any other colours, the first prize was won by Mr. Balfour; second Mrs. Lessing. The best six vases of single Chrysanthemums were shown by Sir Mortimer Singer. His specimens of Mrs. W. Buckingham, Roupell Beauty and Ida Scott were very good; second, Mrs. Lessing. Mr. Gee had the best six bunches of decorative Chrysanthemums, followed closely by Mr W. T. Mattock, Hoadington. The best decorative basket of Chrysanthemums was shown by Mr. W. T. Mattock. In the Amateurs' class for eighteen blooms of Chrysanthemums in six vases, Mr. F. Belcher, Wantage, was awarded the Silver Challenge Cup presented by the late Mr. W. T. Cross. This exhibitor has won the cup for three years in succession. For a group of miscellaneous foliage and flowering plants, Mr. T. H. Rose gained the first prize with an effective arrangement; second, Mrs. Lessing. The six table plants which gained for Mrs. Lessing the first prize were very fine specimens. Table decorations, which are always a popular class at this show, were well represented, and some delicate and dainty arrangements were on view. Mr. W. T. Mattock was placed first with Rose Irish Elegance.

In the Grape classes some excellent bunches were shown. Those of Muscat of Alexandria, shown by Sir Mortimer Singer, were good in bunch, berry and finish, and were awarded the first prize. Alicante variety, shown by Capt. R. B. Brassey, were perfect bunches, and gained for him the first prize in the class for black Grapes. Dr. A. W. Neill had the best nine dishes of Apples; second, Mrs. Lessing. For six dishes of Apples Mr. T. Mattock excelled. The best three dishes of Apples were shown by Mr. W. Jacobs, Highfield.

Mrs. Wadham was a prominent exhibitor in the class for six dishes of vegetables, with some capital produce; second, Mr. R. T. Alden.

TRADE NOTE.

Mr. H. N. Ellison, of West Bromwich, whose exhibits of Ferns and Cacti are a feature at many provincial shows, has added a fertiliser to the range of subjects he offers for sale. Judging from the produce staged in his Gold Medal exhibit at Birmingham on the 6th inst., his "G. and A." fertiliser is well worthy of trial.

Obituary.

Herbert Jones.—A man with plentiful ideas in regard to his gardening work (garden architecture) and an immense driving force in his personality, was Herbert Jones, of The King's Manor, East Hendred, Berks, better known to his friends as "Jones of Bath," who went to his "greater garden" on Saturday, November 3, at the age of 49. He was one of those artists in our beautiful craft in whom the Creator has reposed a little of that divine faculty which creates. Herbert Jones's was the restless, fighting spirit that does things and brooks no opposition, though at the same time it was his geniality and spontaneous gaiety that smoothed away so many of the obstacles put in his path. He had been successively market gardener, flower-grower, actor, quarry owner and architect. His enemies were the common enemies of such personalities—philistines of narrow understanding; the harassing drags on true progress who, unfortunately, are so numerous. He leaves a widow who proposes to complete some of his unfinished gardens, which she is very well qualified to do, having been his confidante and partner in so many schemes—especially those of recent date. *John Wood.*

ANSWERS TO CORRESPONDENTS.

Celery Diseased: *A. D.* Your Celery plants are affected with the disease caused by the fungus Septoria petroselina Apii. See reply to *R. F.* in *Gard. Chron.*, November 3, p. 270.

Cymbidium Lowianum: *E. H. B.* This Orchid is a native of the Himalayas up to 5,000 to 7,000 feet altitude, and is therefore a cool-house plant, but a minimum temperature of 45° should be provided. The plants may be repotted any time after the main display of flowers is over, but it is not necessary to repot them every year. Turfy yellow loam broken by hand, and peat in about equal proportions, or a larger proportion of loam, will provide a suitable compost. Very large pots should not be used. During the plant's season of active growth, occasional watering with weak liquid manure prepared from cow dung will be beneficial to them. Cymbidiums are most useful plants, as they grow and bloom well under varied treatment, and are excellent for conservatory decoration, for their foliage is ornamental even after their long period of flowering has passed. The Cymbidiums do not require to be rested dry, but less water should be given them when growth is not active.

Names of Fruit: *A. C. H.* 1, Franklin's Golden Pippin; 2, Fearn's Pippin; 3, Holland Pippin.—*T. D. A.* Pears: 1, Knight's Monarch; 2, Easter Beurré; Apples: 3, Hambling's Seedling; 4, Castle Major.—*Horti.* 1 and 8, Cox's Orange Pippin; 3, decayed; 4, Yorkshire Beauty; 5, Bramley's Seedling; 6, St. Sauveur; 7, Bedfordshire Foundling; 9, King of the Pippins; 11, Stone's; 12, Ashmead's Kernel; 14, Reinette de Canada; 16, White Westling; 17, Scarlet Golden Pippin; 18, Byford Wonder; 19, Egremont Russet; 20, Hambledon Deux Ans; 21, Golden Harvey (Brandy Apple); 22, not recognised; 25, Warner's King; 27, Royal Russet.

Names of Plants: *F. S.* and *Reader, Highgate.* We cannot undertake to name Chrysanthemums; send specimens to a Chrysanthemum specialist. *E. H. B.* Cymbidium Lowianum; herbaceous plant, Monarda didyma.

Peach Leaves Unhealthy: *F. H.* The unhealthy condition of your Peach leaves is due to an attack of red spider. The foliage was very badly affected, pointing to your having grown the trees in an atmosphere that has been too dry. Early next spring, just as the buds are showing green, spray the trees with a weak solution of lime sulphur, not more than one in about twelve or sixteen parts of water. Keep the atmosphere of the house moist, and use the syringe freely in summer to keep the foliage damp.

The Ecology of Plants.

The study of the "household affairs" of plants by investigating living plants in their natural homes has developed greatly of recent years. This branch of botany, which is known as ecology, has for its object the elucidation of the laws which govern the localisation of the plants of a given country in communities. Some plants, as is well known, have a wide range over a countryside and seem to flourish in the most varied soil conditions; others have a narrow range and exist only in certain kinds of soil. The more these peculiarities of distribution and of association are studied the more there is found to learn about them. Already, although the systematic study of ecology has been pursued for little more than a couple of decades, large numbers of previously unsuspected facts have been brought to light and have contributed to form an imposing body of knowledge. As in other branches of natural history the first step toward the building up of exact knowledge is accurate observation; so it is with ecology. But unlike other departments of botany, such as anatomy and physiology, which require special training and apparatus, the science of ecology may be studied by anyone who knows his plants or is willing to learn how to identify them and who is prepared to prosecute careful and sustained observations into the changes which occur in any given community of plants which happens to be accessible to him. By such studies it will be discovered that the apparently stable community consisting of one or of a few kinds of predominant plants is liable to change. Even a slight change in environmental conditions, as for example a narrow clearing in a wood, provides opportunities for a renewal again of the competition between plants, and once again the struggle is fought out to a finish. Into the clearing come plants from afar, the result of seeds brought by birds and animals or blown by winds, and for a time at least some of the newcomers, previously non-existent, find an asylum in the clearing. Of these some may endure for a long time, others may maintain themselves for but a brief period in their new home. For subtle and often unsuspected changes of environmental conditions follow inevitably from the mere clearing of the part of a woodland. To trace changes such as these and to ascribe them to their causes is an exercise which demands keen powers of observation, much patience and ingenuity. It is to help those who are attracted to such studies that Mr. Tansley, who is prominent among the pioneers of ecology in this country, has written his *Practical Plant Ecology*—a guide for beginners in the field study of plant communities*. From it the attentive reader, after he has become used to the terminology which is inevitable in any science, will gain a clear appreciation of the methods by which ecology is to be studied. He will learn that of plant communities some are large units and constitute plant-associations. Thus over large areas of this country are Beech and Oak woodlands. These woodlands form part of the great deciduous forest association of Europe, and those trees which constitute the chief constituents of the association are known as the dominants. Similarly the common Ling (Calluna vulgaris) is the main dominant of the Heath associations of Western Europe. Other inmates of this or that association, which though habitual to it are less prominent, are known as subordinates. Having determined the approximate constitution of an association the problem of its existence as an entity remains to be attacked. Climate, soil-conditions, the presence of animals and also of other members of the association all have effect in determining the composition and extent of the association. The rough outlines of the association are sketched as it were by climate, but the details of its distribution within those outlines are determined largely by soil conditions. Where, for instance, the soil becomes sandy the Beech and Oak association gives place to another; it may be of Pine forest; and where, as in lower lying ground, the soil is full of stagnant water, yet another plant community, forming an association, arises, one it may be in which Butterwort and Sundew and Bog Moss flourish. In a broad and casual way all of us who are concerned with plants are ecologists, but a perusal of Mr. Tansley's lucid pages will convince us that our knowledge is but fragmentary and may be supplemented with much profit to ourselves by a more thorough study of the known facts of ecology. Among the most interesting chapters in this book is that which gives in outline a survey of British vegetation, and no one with a knowledge of British trees and herbs who reads it can fail to feel that his knowledge has been consolidated and extended. Anyone who has mastered the contents of Mr. Tansley's book and who knows British plants, would be able to tell in the course of a walk the general qualities and potentialities of the soils across which he passed—for by their fruits shall ye know them, and whereas on heavier and good pasture land Poa pratensis, P. trivialis, Lolium perenne and Dactylis glomerata make up the community, on soil of progressive poorness these grasses give place to Bent (Agrostis vulgaris) and the Sheep's Fescue (Festuca ovina) and it may be the Sweet Vernal Grass (Anthoxanthum odoratum). On such land, if grazing ceased, Heath and ultimately woodland would appear, and indeed in such places Calluna and Erica may be found in patches when grazing is intermitted for a time. Down on the more acid, peaty soil the dominant plants are the Silver Hair Grass (Deschampsia flexuosa) or the Mat Grass (Nardus striata) or in yet damper places the Purple Moor Grass (Molinia caerulea). In soils rich in lime the grasses are again different — Avena pratensis, A. pubescens and Triestum flavescens; and if the soil be dry and chalky there will be a closely grazed turf of Festuca ovina or F rubra var. fallax, with many herbaceous weeds characteristic of chalky soil.

* *Practical Plant Ecology.* By A. G. Tansley, F.R.S. London: George Allen & Unwin, 1923. 7s. 6d. net.

War Buildings in Regent's Park.—The First Commissioner of Works, in reply to a question by Major Barnett in the House of Commons, stated that the buildings occupied by the Imperial and Foreign Corporation, Ltd., in Regent's Park are being evacuated and will be demolished as soon as practicable and the site restored to public use. Owing to the large amount of work to be done on the site it is not anticipated that this portion of the Park can be resown with grass before the autumn of next year.

A Memento of Two Distinguished Biologists.—Dr. Michael Foster, of Trinity College, has presented for use in the Balfour Library, Cambridge University, the desk habitually used by Francis Maitland Balfour. After its death it was presented to Sir Michael Foster, who habitually used it until his death. It thus recalls two of the chief founders of the biological schools of the University.

Thornless Stock for Roses.—An American firm, the S. R. McKee Nurseries and Rose Gardens, Jacksonville, Texas, has, according to the *National Nurseryman*, U.S.A., a thornless form of Rosa canina, which they are offering as the McKee Thornless Rose stock. Three spineless plants were discovered some years ago growing amongst a large batch of Rosa canina, and they were set aside and propagated. The thornless character proved to be constant, and Messrs. McKee, who are large Rose growers, consider their new stock to be superior to all others.

National Chrysanthemum Society.—The next annual exhibition of the National Chrysanthemum Society will be held at the Royal Horticultural Hall, Westminster, on November 6 and 7, 1924.

The Cold Weather.—The frost experienced on the morning of November 8 was the sharpest recorded for many years in the early part of November. In some districts the thermometer fell to 11° F. At Kew the shade temperature fell to 22° F., which is said to be a record for the first ten days of November, being 2° lower than the previous record on November 10, 1921.

Sir John Russell.—Sir John Russell, Director of the Rothamsted Experimental Station, has proceeded on a special mission to the Sudan, where, in association with Dr. H. Martin Leake, Director of Agriculture for the United Provinces of India, he will advise the Sudan Government on its agricultural policy. In approaching these two experts the Sudan Government has been actuated by the desire to get the best possible advice as to the organisation and direction of the agricultural research work which will be undertaken in connection with the Cotton growing industry in the Sudan. When the first instalment of the irrigation scheme in the Gezira plain, south of Khartoum, is finished, 300,000 acres will be put under irrigation, of which 100,000 acres will be under Cotton cultivation. The total scheme is said to be capable of development over an area of three million acres.

Garden Pictures at the Englishwoman Exhibition.—There was much to interest the lover of gardens in the exhibits of Miss Minnie Aumonier, at the Englishwoman Exhibition of women's handicrafts at the Central Hall, Westminster, last week. It was a pleasure to step in from the cold, frosty air, and find on a stall a wealth of drawings recalling all the warmth and beauty of the summer garden. Besides a number of fine original paintings, there were colour prints and cards, nicely executed, from garden sketches; among other things were some pretty invitation cards, with a floral design, to be sent from one garden-owner to another. *Gardens in Sun and Shade*, the book of garden verse compiled by Miss Aumonier, was on sale in its third edition. Another exhibit which was of great interest to horticulturists was Messrs. Winder and Thomson's scale model of a small house and a three-quarter acre garden, planned to make the very most of the space, and to provide for every kind of pleasure ground, though naturally on a small scale. Rose garden, lawn, shrubbery, formal garden, all were represented, real dwarf trees being used where possible, and very small artificial flowers, with little pieces of statuary and tiny stone seats.

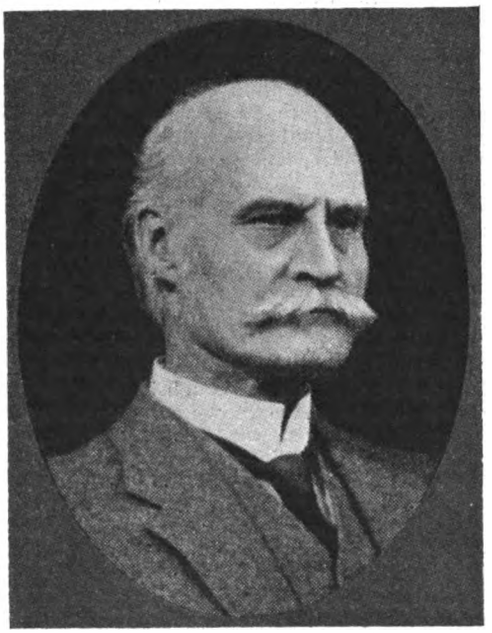
National Dahlia Society's Annual Meeting.—The annual general meeting of the National Dahlia Society will be held in the Royal Horticultural Hall, Westminster, on Tuesday, November 27, at 3 p.m.

The Preservation of Wood.—According to the *Chemical Trade Journal*, methods for the preservation of wood date back from very early times. The ancient Egyptians used antiseptic oils for the purpose. Amongst the earliest attempts at wood preservation in this country were those by Burnett in 1838, who introduced the use of zinc chloride; Wolman in 1906 patented the use of certain fluorides in conjunction with other salts; and since then hundreds of patents on the subject have been taken out. The most popular method at the present time is that of creosoting timber, but it has objections in that it makes the timber odorous and inflammable. The article deals with various methods of impregnation, and the results obtained from the use of various salts.

Iris unguicularis.—Mr. David Chaplin, Frognal Gardens, Sunninghill, Ascot, writes to inform us that Iris unguicularis opened its first flower there on the 14th inst., whereas in 1922 the first flower of this Iris appeared on October 16.

The Scottish Potato Crop.—Returns collected by the Ministry of Agriculture for Scotland, representing about seven-eighths of the total area of Potatos on agricultural holdings in that country, show that 119,100 acres were planted with Potatos this year, representing 17,300 acres of first earlies, 19,100 acres of second earlies, and 82,700 acres of main crop varieties. The total area is 20,400 acres less than last year. The acreage of first earlies shows an increase of 800 acres, but there was a reduction of 5,900 acres in the case of second earlies; the proportion of second earlies in the total has declined in two years from 23 to 16 per cent. Epicure is still the most popular early variety, although there was a slight reduction in the acreage of that sort cultivated this year, but the acreage of Sharpe's Express was practically double, while Duke of York showed an increase of about one-third. Great Scot is the most favoured second-early variety. Of the main crop sorts Golden Wonder showed an exceptional increase of 58 per cent.; Arran Chief, although still the most largely grown of all the varieties, declined by 29 per cent., and King Edward VII. showed a reduction of 17 per cent. The greatest reduction was in the case of Tinwald Perfection—about 54 per cent. Considerable increases are recorded in the cases of Roderick Dhu and Field Marshal, but there were no very great additions amongst other newer varieties. The chief main crop varieties cultivated were Arran Chief, 21 021 acres: King Edward VII., 16,899; Golden Wonder, 12,403; Kerr's Pink, 10,988; Up-to-Date, 3,594; Majestic, 2,713; Sutton's Abundance, 2,437; Tinwald Perfection, 2,372; Champion, 2,126; Langworthy, 1,916; Field Marshal, 1,143; Crusader, 1,084; other varieties, 4,029 acres.

Mr. Frederick A. Gardiner.—After occupying an important position with Messrs. J. Carter and Co. for fifty years, Mr. F. A. Gardiner has recently retired, and we take advantage of the occasion to publish his portrait and a few particulars of his career. Mr. Gardiner was born at St. Osyth, a very old Essex village, at one time of considerable importance, but now mainly agricultural. Messrs. Carter and Co.'s seed farm was formerly situated in the district, Mr. Gardiner's father being manager, hence it may be said that Mr. F. A. Gardiner was born in the business. He commenced his business career with his father—who devoted many years of his life to introducing novelties—and he has served the firm of Messrs. J. Carter and Co. ever since. He spent three years on the farm at St. Osyth, and came to London in 1873, when the firm had its headquarters in High Holborn. During the ensuing fifty years Mr. Gardiner has become well known to all classes of horticulturists, not only in Great Britain but on the Continent, as for over forty



Mr. F. A. GARDINER.

years he has made annual visits to all the expert European seed growers who work on progressive lines and produce novelties worthy of attention. Mr. Gardiner is a well-known personality at all the important exhibitions, and a most frequent visitor to those of the Royal Horticultural Society. Before Mr. F. A. Gardiner came to London he had taught himself shorthand, an accomplishment which few had acquired in those days, and acted as secretary to the head of the firm, Mr. E. J. Beale, who prided himself in being one of the first business men to employ a shorthand writer. In addition to shorthand, Mr. Gardiner acquired a good knowledge of French and German, which has stood him in good stead, and these attainments, coupled with fine business acumen and an agreeable personality, soon advanced him to the front rank in the seed world. Mr. Gardiner has, moreover, a fine commanding presence, and represents a very fine type of Englishman. He is always ready to offer his ripe experience for the benefit of others, and is a member of the Council of the Agricultural Seed Trades' Association (occupying the position of President several years ago) and of the Horticultural Trades' Association. He rendered much valuable service to the country during the war as a member of the Agricultural Relief of Allies Committee, whilst he also served in an advisory capacity in connection with the Seeds Committee of the Ministry of Agriculture. For some time Mr. Gardiner was a member of the Committee of the Royal Gardeners' Orphan Fund. He is a fellow of the Linnean Society and also of the Royal Agricultural Society. Mr. Gardiner retires from the position of manager of Messrs. Carter's wholesale department to enjoy a well-earned rest, and his many friends will be glad to know that although not so robust as when younger, he still enjoys fairly good health, and hopes to keep in touch with them at flower shows and other horticultural functions. At a luncheon given in his honour a few days ago, Mr. Gardiner was presented with a complete set of the *Encyclopaedia Britannica* and a timepiece, suitably inscribed, from the staff of Messrs. J. Carter and Co., together with a gold watch and chain from the principals of the firm.

Importation of Potatos into Uruguay.—The Ministry of Agriculture is informed that owing to the low production of Potatos in Uruguay this year there may be a market for British Potatos in that country. In 1922, the importation of Potatos into Uruguay amounted to nearly 36 million kilos (35,500 tons), of which about 32 million came from the Argentine. France contributed nearly 1 million kilos and the United Kingdom 2¼ million. The trade is a new one for this country, but if a high standard of produce is maintained and care is taken in transportation it offers possibilities. British exporters are advised to be liberal in their trading terms and to ship on consignment, under agreement that in the case of the consignment turning out badly, resort should be had to arbitration by the British Chamber of Commerce in Uruguay. The Argentine imports do not materially interfere with the British imports, as the former usually arrive between January and August, ending in the middle of September at the latest.

Appointments for the Ensuing Week.—Monday, November 26.—National Chrysanthemum Society's Floral and Executive Committees meet. Tuesday, November 27.—Royal Horticultural Society's Committees meet. Wednesday, November 28.—Mitcham, Tooting and District Horticultural Society's meeting. Saturday, December 1.—Blackburn and District Horticultural Society's meeting.

"Gardeners' Chronicle" Seventy-Five Years Ago.—*Fallen Leaves.*—What shall I do with my leaves? Are they good for anything? asks a correspondent. Do with them! good for anything! Why treasure them to be sure, as if they were coin of the realm; they are good for everything which a gardener has to do. They are the best of all shelter, the best of all materials for bottom-heat, the best of all soil, the best of all drainage, the best of all manure. It is true they contain little or no nitrogen, but they rot quickly, are full of saline matters, on which everything that bears the name of plant will feed gluttonously, and from their peculiar structure allow air to pass in and water to pass out with perfect freedom. If we wish to know what leaves are good for, we have only to burn them and see what a quantity of ash they leave behind. All that ash is as much food for other plants as beef and mutton are for us. It is the material which Nature is perpetually restoring to the soil in order to compensate for the waste which is produced by the formation of timber. In wild land, trees are annually thus manured; were it otherwise a wood would be a roof of life overshadowing a floor of death. If we can remove the leaves from our plantations, it is only because of the artificial richness of the soil in which they grow. This sufficiently indicates the value of leaves, which are in truth hardly less important in their death than they were in their life, though in a different way. *Gard. Chron., November* 18, 1848.

THE ALPINE GARDEN.

LINARIA ORIGANIFOLIA.

THIS is a valuable rock garden plant, as it blooms in the late summer, when most plants have faded, and its flowers will often be among the last to linger when autumn passes towards winter.

Linaria (syn. Chaenarrhinum) origanifolia is a Spanish high-alpine, a semi-prostrate plant, some 5 inches in height, with dark-green foliage, and rosy-violet blossoms of the characteristic Snapdragon type, produced in profusion throughout the above period. The plant appears to be quite hardy, and will prove permanent in almost any free soil, in a situation exposed either to full sun or in half-shade.

BELLIS ROTUNDIFOLIA COERULESCENS.

THIS pretty little Daisy was among the first of the spring flowers in the rock garden, and it has never been out of bloom since that time. Even at the end of October, it had a few flower buds ready to greet the first sunny day. B. r. coerulescens is not, perhaps, perfectly hardy, the type species being a native of the Atlas; but it is quite robust enough to stand an average winter in most places, provided it is planted in a sheltered corner and well-drained soil.

In its flat rosettes of foliage, B. r. coerulescens is much like our common Daisy of the fields, but the rounded leaves are slightly scalloped and grey with silky hairs. The flowers, which are borne in great profusion throughout the season, are about 1 inch in diameter and of a most delightful shade of pale lavender blue. In some gardens B. rotundifolia and its variety are said to spread rather too freely, especially when grown in the moraine, but I have never been troubled in this way. *A. T. J.*

FUCHSIA PROCUMBENS.

THIS is an attractive little creeping species which has proved quite hardy enough for our winters, on one or two occasions withstanding nearly 20° of frost without much injury. F. procumbens makes a close mat of pale-green, delicate-looking foliage about 4 inches in height, from which slender runners radiate in all directions, rooting to the extent of 15 inches or more from the parent.

About midsummer the plant produces numbers of flowers—cylindrical, honey-coloured tubes, the reflexed segments being chocolate-coloured, with a bright daub of arsenical green at their bases.

When these curious and interesting flowers are over, they are succeeded by round fruits, which, green at first, change to crimson and finally ripen in a deep plum-red. By this time they are as large as small Gooseberries, and look very striking amid the golden-yellow which the foliage assumes before it falls. In this garden F. procumbens enjoys a cool, moist, but well-drained, sloping ledge, a dressing of old manure, grit, and loam being given in the spring. It is probable that this delightful plant would winter out-of-doors in most places, but, being dwarf and deciduous, protection may easily be afforded it in very cold weather.

This Fuchsia makes an admirable subject for growing in baskets in the greenhouse or alpine house. *N. Wales.*

SYNTHYRIS RENIFORMIS.

SYNTHYRIS reniformis is a charming little alpine with somewhat kidney-shaped, notched leaves and racemes of pretty blue flowers, a good plant presenting a pleasing sight when in full bloom. It blooms frequently in February and March, especially when in a sunny, sheltered position. It is not difficult to grow in the soil generally accorded to other alpines, but likes a fair amount of moisture during the spring and summer. It grows only some four or six inches high. A native of north-west America, it has proved hardy in our climate for a number of years. *S. Arnott.*

INDOOR PLANTS.

HUMEA ELEGANS.

PLANTS of Humea elegans that were raised from seed sown during August should now be ready for shifting into 48-sized pots, in which they should remain until early in the New Year. Watering the roots should be done carefully at all times. The plants should be grown in a position near to the roof-glass, and they should at all times be kept perfectly cool, as close, stuffy atmospheric conditions soon ruin them, and render them subject to attacks of aphis. If attacked by aphis the plants should be dusted with tobacco powder, as this plant is very impatient of fumigation.

Where smaller quantities of plants are required, it will be sufficient to insert the cuttings in pots of sandy soil, standing them in a propagating case. If slight bottom-heat is available the cuttings will root quickly, but heat should be used very carefully, as too much warmth results in weak, spindly growth. When well rooted, the plants should be placed singly in small receptacles, using a light compost for the first potting. When lifted from a sand bed to be potted they require very careful handling. After potting they should be kept close for a week or so until they become established. *C.*

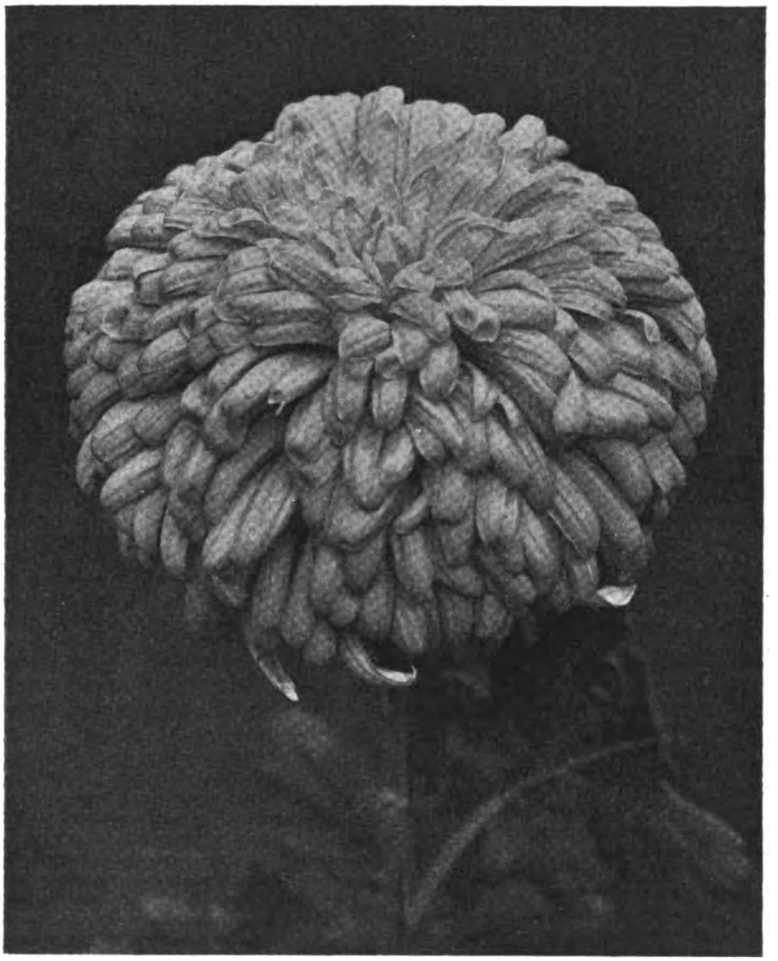

FIG. 110.—CHRYSANTHEMUM RADIANT. R.H.S. AWARD OF MERIT, NOV. 13 (SEE PAGE 300).

CARNATIONS.

CARNATIONS that are about to flower should be watered with diluted liquid manure or soot water on frequent occasions, and fed occasionally with a suitable fertiliser. Concentrated fertilisers of all kinds should be applied with judgment, for if manuring is overdone it may result in the flowers damping. The house should be kept at a temperature of 45° to 50°, and, during dull weather it is essential to maintain a buoyant atmosphere. To attain this condition gentle warmth should be maintained in the hot-water pipes, with a little ventilation on all possible occasions when the weather is favourable.

Continue to insert cuttings until the required stock is obtained; care should be exercised in selecting the cuttings, the best shoots for the purpose being those growing about half-way up the plant, cuttings from the base or near the top of the main shoot generally being unsuitable.

Where a large stock of Carnation plants is required it is best to prepare a bed for the cuttings, formed of several inches of clean sand and covered with a frame to support loose panes of glass, which should be turned every morning.

PENTAS.

CUTTINGS of Pentas carnea (syn. Quartiniana) root readily in sandy soil in gentle heat in early spring, and will develop into bushy plants by the end of summer, set with flower buds for a winter display. It is of a somewhat straggling habit, and when established in small pots should be stopped at the first pair of leaves, and kept pinched as growth proceeds. The pink flowers are borne in terminal cymes, in size and appearance similar to those of the Bouvardia. If desired, the plants may be grown for a second season, in which case, after flowering, they should be cut back, placed in heat, and when breaking freely, shaken out and repotted in a compost consisting of loam and leaf-mould with a little sand added.

During the summer months they may be grown in a cold pit or frame, removing them to the greenhouse in early autumn. The root system is not extensive, and six-inch pots are large enough for yearling plants. When established in their flowering pots the roots may be fed at intervals with liquid manure or a quick-acting fertiliser. *Fred W. Jeffery.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Pleione.—The Indian Crocuses, as these Orchids are often termed, are of easy culture, and few, if any, of our smaller Orchids are more beautiful when well grown. Considering the quantity of flowers they produce in the dull season, and the beautiful effect afforded when they are used for decorative purposes, space should be found for them in every collection. The flowers of these Orchids keep long in good condition, when used for room decoration, which they adapt themselves to much better than many other plants, whilst their flowers are most useful for buttonholes. P. maculata, P. lagenaria, P. concolor, P. praecox, and P. Wallichiana are now passing out of bloom, and the cultivator will observe that those green shoots from the centre of which the blooms have sprung will, under proper treatment, develop into strong-flowering pseudo-bulbs. As soon as the flowers have faded, the new shoots will already have produced from their bases a number of small white roots, and, as these roots lengthen rapidly, no time should be lost before doing the necessary repotting, for, if the operation is delayed until the roots are long, many are certain to be injured, as they are easily broken. Shallow pans are the best receptacles, as they are easily suspended from the roof, and the plants need plenty of light, especially during the short days of winter. The pans should be well drained to permit the free passage of the large quantities of water these plants require when in full growth. Pans of 8 to 10 inches in diameter, holding about 18 to 20 pseudo-bulbs, will be found useful sizes. In repotting, instead of dividing the growths, it is advisable to place them in clumps, arranging the pseudo-bulbs almost touching each other. The potting material should consist of equal parts of fibrous loam, peat, and Sphagnum-moss, well mixed together, with the addition of a fair quantity of coarse silver sand. Over the crocks place a layer of Moss to prevent the finer parts of the compost getting down into the drainage; then fill the pan to within an inch of the rim with compost, on which the plants should be placed, the space between the bulbs and the sides of the pan being filled with compost; also, where possible, some of the roughest of the material should be placed between the pseudo-bulbs. In filling in around the bulbs it is desirable to work some of the heads of Moss in with the compost to grow, as Moss provides a wholesome moisture around the plants, in which they luxuriate.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Cordon Trees on Walls.—The roots of Cordon fruit trees should be under control or the fruits will be badly coloured. Should they exhibit this defect the trees should be lifted and replanted nearer the surface, reducing any strong roots. The soil, especially under and around the roots, should be rammed thoroughly. The bole of the tree should be set about nine inches from the wall. The main roots will not then be so liable to suffer from extreme dryness, which a wall often causes. It further offers greater resistance to attacks of woolly aphis. In planting it is very important to see that all the roots are set out regularly, taking care that they do not incline in a downward direction. In the case of large trees it may not be possible or desirable to lift or even root prune the whole of the roots in the one operation; half the roots may be pruned on the one occasion, deferring the remainder of the work for the next season.

Figs.—Fig trees often grow too rampantly, pointing to the need of severe root-pruning. If the root medium is mixed with stones and broken bricks placed on either side, this will result in better ripening of the wood. Grid-iron trained trees are useful for growing on pergolas. The shoots of such trees are often too close to permit of air and light entering freely after the spurs have extended a few seasons. A suitable distance from shoot to shoot is 16 inches. The foliage of certain varieties is much larger than that of other sorts, but the distance or width suggested is one which can be taken as an average.

Staking.—After planting, it is very important that trees should have proper support. Large trees should be secured to three stout pegs driven in triangle shape, 4 feet upwards away from the tree, according to its height, and string or wire attached to the pegs and the tree. A band of hay or a piece of sacking should be placed around the stem of the tree to prevent chafing the bark. This precaution is essential if long stakes are used and similarly placed; for smaller trees one stout stake may be sufficient to hold the tree in position.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Dracaena Goldieana.—This beautiful and distinct species does not seem to be common in gardens at the present day. Well grown specimens are very decorative. When the plants lose their lower leaves and become leggy, the stem should be cut half-way through just under the leaves, and a handful of Moss tied around the cut portion. If this is kept moist, and the plant kept somewhat dry at the roots, fresh roots will develop above the cut on the stem. The top may then be cut off and placed in a suitable-sized receptacle, standing it in a close case until the roots have grown freely in the compost. If the old stem is cut into portions, and the latter laid in fibre in a warm case, a number of them will form roots and make young plants, although this species is by no means so easily propagated as most Dracaenas and Cordylines. D. Godseffiana is a very different looking plant. It throws up a number of slender shoots, forming a bushy, well-furnished head, and is very useful for decorative work. This species is easily propagated by means of cuttings, which root readily in a warm propagating case.

Watering.—During short, dull days watering requires to be done with care. Choose the early part of the day for watering, so that the plants are not too wet over night. At this time it is safer to keep plants on the dry side, taking care, of course, that they do not suffer from want of water. Plants may also be grown successfully in a lower temperature if they are kept on the dry side. Every favourable opportunity should be taken to afford ventilation, even if it is only for a very short period during the day. All plant houses should have bottom ventilators, which should never be closed entirely except during very severe weather.

THE FLOWER GARDEN.

By C. TURNER, Gardener to Emily, LADY AMPTHILL, Ampthill Park, Ampthill, Bedfordshire.

Herbaceous Plants.—The planting of hardy herbaceous plants may be done more or less successfully throughout the greater part of the year—certainly during over eight months if circumstances demand it. But it is best to get the work done as soon as possible before Christmas, or early in the spring. Where existing borders have to be rearranged and replanted, it is sometimes necessary to sacrifice what may be called secondary flowers on some plants, and even the chief bloom of the late-flowering subjects, to enable the work to be proceeded with. This applies particularly where alterations are being done on an extensive scale and have to be completed by a given time One sound reason in favour of early planting is that it allows the plants time to become established in the soil during the cool and more or less moist season of the year, and, being thus early established, these plants are better able to withstand drought caused by drying winds and the hot days of spring. It is, perhaps, as much a matter of convenience as of opinion as to how long a permanent flower border should be allowed to remain undisturbed. Three to four years is often cited as being a sufficient time, but such borders may be left undisturbed longer, and with no serious ill-effects on the most vigorous plant types. However, an occasional overhauling is advisable, if only to curtail the strong-growing plants, nurture the choicer, and introduce fresh variety. Borders for the growing of perennial plants should be thoroughly well made, and enriched proportionately to the kind of soil dealt with Entirely new borders should be prepared beforehand, and the arrangement for planting drawn up, so that the plants may be put in their positions directly they are received from the nursery. Mulching the surface is best done when hot weather is about to set in, but a light covering of strawy material may be placed around the roots of delicate subjects at planting time.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Turnips.—The plants growing in the open should have any dead or decaying foliage picked off, and a little soil drawn up to the roots to prevent them from getting frozen. A few of the largest roots may be lifted, and placed in a shed with sufficient sand or fine soil over them to keep them plump and fit for use. Veitch's Red Globe is an excellent late Turnip; it is hardier than the white type, and keeps in good condition if treated as advised.

Tomatos.—Young Tomato plants intended for early fruiting should be grown on a shelf near the roof-glass in a fairly warm house, where they may be given a little fresh air on suitable days. Give the roots only sufficient water to keep the plants growing, and support each plant with a neat stake. Fumigate the house occasionally to keep down insect pests.

Parsnips.—A few Parsnips may be lifted and stored in sand in case of bad weather, but they are better when dug from the open ground as required. It is a good plan to place litter or rough leaves over a part of the bed to permit of digging the roots in frosty weather.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

The Orchard House.—The value of an orchard house is fully realised after the vagaries of the present season, the protection afforded against inclement weather, even if the house is unheated, being sufficient to ensure a crop of fruit. If the house is heated, the prospects are materially enhanced, as the atmospheric conditions can be regulated to suit the requirements of the trees. Heated orchard houses are chiefly devoted to trees grown in pots, and after these are turned out-of-doors, other use may be made of the house until the time arrives for starting the trees again. Assuming this to be the case, the first opportunity should be taken to thoroughly cleanse the interior of the house. If fruit trees are planted in the house, any necessary work in respect to planting, pruning, spraying, etc., which has not yet been done, should receive early attention, and this work should also be done in houses that are unheated. Trees in an unsatisfactory state of health should be removed and substituted by others from the reserve stock. The soil should be kept moist, as the roots are more or less active throughout the year. When forming new borders, the requirements of the various trees should receive consideration. For stone fruits, old mortar rubble or broken plaster should be incorporated with the soil, and this should be, for preference, rather heavy, but good results are obtained by using soil of a lighter character, provided the roots receive a good mulch and plenty of water during the season of active growth. Apples prefer a moderately heavy loam, and Pears loam of a lighter nature.

ORCHID NOTES AND GLEANINGS.

ONCIDIUM VARICOSUM.

IN the groups at the Orchid show at the Royal Horticultural Society's meeting on October 30 the beauty of this fine old species was well in evidence, the numerous branched spikes giving a marked effect. The species is a native of that most prolific home of Oncidiums, the highlands beyond Rio de Janeiro, from whence come some of our best cool house Oncidiums, including O. Marshallianum, O. concolor, O. crispum, O. sarcodes and their allies. It first made its appearance in England when a plant of it flowered in the Chiswick Gardens of the Horticultural Society in 1849. The variety Rogersii flowered in the collection of Dr. Rogers at East Grinstead, who obtained a First-Class Certificate for it at the Royal Horticultural Society's meeting on December 15, 1868.

As in many of the Oncidiums the labellum is the most conspicuous part of the flower, and in O. varicosum it varies much in size and form, the variety Rogersii, which is about two inches across, having the labellum divided into four lobes by three clefts, while the original has but one cleft in front.

All the flowers are of bright yellow colour, and two of the finest forms, Charlesworthii and Westonbirt variety, have red blotches at the base of the lip. The varietal name Rogersii is commonly used for the best type, although few appear with its distinctive features. The species and its allies are among our best cool house Oncidiums and last a considerable time in bloom, whilst their value for exhibition in a mixed group at this season was clearly demonstrated on the occasion referred to.

EPIDENDRUM ENDRESIO-XANTHINUM.

THE first inflorescence of a new cross between the dwarf white Epidendrum Endresii of Costa Rica, and the yellow Brazilian E. xanthinum, is sent by H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), who has been one of the few to grow the slender white E. Endresii successfully, and now produces its second hybrid, the first being the E. Endresio-Wallisii, of Messrs. Veitch. The flowers, which are about one inch across, are larger than those of E. xanthinum, which, however, appears in the taller growth and the colour of the light chrome-yellow flowers. The lip is intermediate in form, the parts less fringed than in E. xanthinum, and with a slight trace of the few mauve spots of E. Endresii. *J. O'B.*

THE BULB GARDEN.

THE KING'S SPEAR.

THE Asphodel, like the Amaranth, is frequently alluded to in works of poetry and imagination and has a great claim to antiquity and sentiment, yet the family is but seldom found in our gardens to-day. There is a beautiful variety in the Bog Asphodel (Narthecium ossifragum), which flourishes freely in damp and marshy soil in a certain locality in Keston, where, hard by, the little Sundew thrives. It is not known now how the title ossifragrum (bone-breaking) came to be applied—probably some fancy which arose in the distant past. I have many times admired the Narthecium, both for its graceful bearing and star-shaped yellow flowers, and have been tempted to bring home roots, but with every care expended upon it, it has never done well, and I am quite unable to cultivate it with any success. I have come to the conclusion that it pines for its native, pure air, and will not otherwise be satisfied.

The Asphodel is a native of Europe and hardy in our country. Two varieties are perhaps better known than the others, viz., luteus and ramosus. The former bears a yellow inflorescence, as its name implies, and flowers in the summer, attaining a height of about 3 feet. It is a stately plant, but generally regarded as somewhat inferior to ramosus, the King's Spear. This will reach a similar height or more, and throw out in June numerous branches from the flowering stem bearing spikes of white bloom, which are beautiful and attractive. The foliage is stiff, like that of the Tritoma. It gives no trouble in cultivation and does well in a stiff soil, but I think would be happier if given a lighter medium. It should be planted in autumn and lightly covered with a little old manure and not disturbed until overcrowded. I call to mind a large patch of A. ramosus growing in a cottage garden in Essex years ago. It formed such a pleasing and satisfactory picture that I remember it to this day, and have every confidence in recommending it as a welcome and ornamental contribution to the garden. *T. D. T.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS**, 5, Tavistock Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

STERILITY IN LILIES.*

THE tendency of many species of Lilies to produce seed irregularly, sparingly, or even not at all, is well exemplified in the old familiar Tiger Lily of our flower gardens. This species has been in cultivation in Europe since 1804; it thrives and blooms abundantly over a wide area; it has been observed in cultivation and also apparently wild in its native home (China and Japan) by persons interested in discovering whether fruits were formed. Yet the author is aware of only two references to the pods and seeds of this species, and the accuracy of these is somewhat doubtful. On the other hand, its fruitlessness has repeatedly been observed wherever it has been grown. The Tiger Lily is one of the most striking examples that can be cited of a plant which blooms in abundance, but is propagated only by vegetative means.

THE LAW OF COMPENSATION.

A ready explanation has long been offered by gardeners and botanists for the condition of sterility found in such plants as the Lilies. It has been generally believed that they are physically unable to develop seeds because the bulbs and bulblets use the available food. The tiny embryos were assumed to be virtually starved to death. This explanation of the condition has seemed so obvious and so correct that it has received the sanction of the most critical authorities, and is stated in Darwin's law of compensation and in Goebel's law of correlation. But this simple and apparently very satisfactory explanation we now know to be entirely wrong, at least in its application to the condition of sterility in the Lilies. Obviously the best evidence of the truth of this statement is the fact that these usually fruitless plants have been shown to be fully able to produce capsules and seeds. Such evidence is in most cases readily obtained.

STERILITY DUE TO INCOMPATIBILITY OF POLLEN.

For a period of about fifteen years Focke persisted in attempts to obtain seed of L. bulbiferum. He secured bulbs from various parts of northern and western Germany, and made many cross-pollinations of their flowers, but obtained at best only a few poor capsules. Finally, bulbs were secured from Switzerland, and with the use of pollen of plants grown from them pods and seeds in abundance were matured on the hitherto fruitless plants.†

The writer has had much the same experience with other species of Lilies. A fine large cluster of L. croceum, all descended from a single bulb, growing in the New York Botanical Garden, completely failed to set seed for eight consecutive years. The numerous flowers that appeared each year were self- and cross-pollinated, but there was never even a slight enlargement of any of the ovaries. In 1921, plants of L. elegans bloomed at the same time as the cluster of L. croceum, and their pollen was used in pollinations. Fine large pods then developed, and these contained many viable seeds. In 1922 these plants of L. croceum also yielded pods and seed by cross-pollination with another strain of the same species. Hence these plants were fully able to mature fruit, and their pollen was likewise able to function in certain reciprocal crosses.

In an effort to discover compatible fertilisations that would produce seed on the Tiger Lily, bulbs of this species have been secured from widely separated localities, some even coming directly from apparently wild plants in China. All plants grown from these have, so far as tested, failed to yield fruits either by self-pollination or by cross-pollination between the different strains. Capsules also failed to form

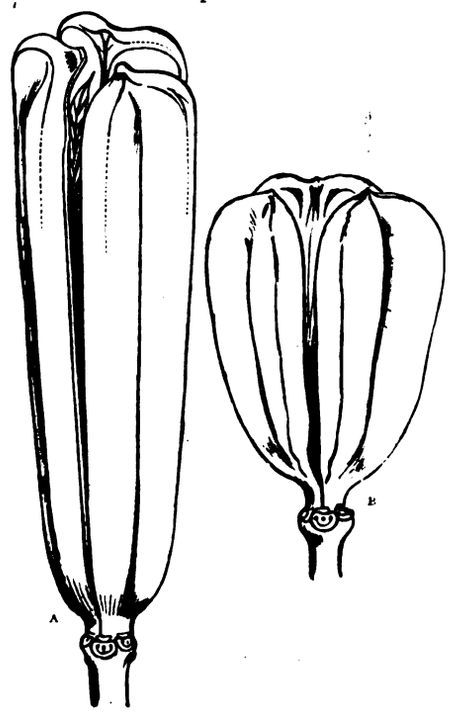

FIG. 112.—CAPSULES AND SEEDS OF (*a*) LILIUM AURATUM AND (*b*) L. SPECIOSUM.

when pollen of such species as L. canadense, L. superbum, L. Henryi, L. speciosum, L. auratum, and L. Humboldtii was used. To pollen of L. warleyense, the ovaries of the Tiger Lily began to enlarge and become upturned, but the capsules did not develop fully, and yielded no seeds. But when pollen of L. Maximowiczii was used fine pods were readily obtained. Potted plants, plants grown in the open, old plants of vigorous vegetative growth, and plants from bulblets blooming for the first time have all produced fine pods from the flowers thus pollinated. Yet on these same plants complete failure resulted from all attempts to produce seed by self-pollination.

It is clear that these usually sterile plants are able to form fruit and seeds, and that their pollen is potent, provided there are compatible relations in fertilisation. The bulb and the bulblet-forming habits of growth, and of vegetative propagation do not render seed production impossible. The sterility is that of physiological incompatibility in fertilisation, a well-marked type which is also seen in numerous species that naturally reproduce exclusively by seeds, and is by no means peculiar to plants that reproduce vegetatively.

In the course of experimental studies with species of Lilium now in progress at the New York Botanical Garden, controlled pollinations have been made for plants of twenty-eight species. In every species thus far studied seed production is decidedly limited by incompatibility in fertilisation.

The phenomena of incompatibility are well illustrated by the results obtained with L. regale, a splendid and beautiful Lily recently introduced from China. Of the ten plants tested, nine were self-incompatible and one was self-compatible. Cross pollination between plants sometimes succeeded and sometimes failed. The same sort of results were also obtained with plants of L. speciosum, L. candidum, L. Henryi, L. parvum, L. tenuifolium, L. Humboldtii, L. Kellogii, L. warleyense, L. longiflorum, and L. auratum.

No capsules have yet been obtained on plants of L. Hansonii, L. Parryi, L. Maximowiczii, and L. chalcedonicum, but in all cases except that of L. Hansonii only a few plants have been tested, and these were all obtained from a single source.

CROSS-INCOMPATIBILITY.

It is to be noted that crosses between different plants of a species in which there is self-compatibility are also frequently incompatible. One is, however, not at all certain that any two plants of a variety of Lily are really of different seed origin, for they both may be the daughter bulbs of a single parent plant, and thus belong to a single clone. If the original plant grown from seed was entirely self-compatible, then one may expect the members of the clone to fail to set seed in crosses. The condition is similar to that encountered in fruit-growing, when an entire orchard of a self-incompatible variety of Apple or Cherry fails to set fruit unless proper cross-pollination with another variety is provided for. Without doubt it is often the extensive vegetative propagation of a single self-incompatible plant that makes it difficult to secure compatible crosses from apparently different plants of certain varieties of the Day Lilies and the true Lilies.

Seedlings of L. longiflorum have been grown to the flowering age in the course of the studies here reported. Many of these were self-incompatible, a few set seed with their own pollen, and many crosses with other plants failed. Such ranges of variation in regard to the compatibilities of sister plants of seed origin are very common in many species.

OTHER TYPES OF STERILITY.

There are other types of sterility in the Lilies besides that of incompatibility. In certain hybrid varieties, L. Batemanniae for example, there appears to be complete impotence, a type of sterility that is very characteristic of hybrids; the spores, both in pistils and stamens, are aborted and functionless in any relation. A one-sided abortion characteristic of intersexes has also been noted in at least one species.

HOW TO OBTAIN SEED.

The principal condition limiting seed production in the Lilies is that of incompatibility. When seed is desired from plants that are yielding no seeds because of this condition, it is simply necessary to obtain other stocks of the same species and interplant so that cross-pollination may be effected by insects, or by hand. If the new stock is cross-compatible, seed will readily be produced, but if it is not, seed will not be formed until stock which is compatible is secured. Usually compatible clones may readily be obtained, and often a single planting of commercial bulbs contains such a mixture of stocks, but for certain species and especially for L. tigrinum, L. Hansonii, and L. candidum, it seems somewhat difficult to secure compatible fertilisation.

One of the principal sources of failure in establishing a planting of Lilies in one's garden is the poor physical condition of bulbs when received. Especially is this true when bulbs are imported. In many species the dormant period is very short or is entirely absent. With the death of the top there is usually continued development of the daughter bulbs, and growth of feeding roots. Without doubt the best means of securing healthy and vigorous bulbs of many species at least, is to grow them locally either from seed or by vegetative propagation, and to transplant so that the bulbs are only out of the ground for a short time when they are most nearly dormant.

* "Sterility in Lilies," by A. B. Stout, of the New York Botanical Garden, New York City, and published in the *Journal of Heredity* (Organ of the American Genetic Association), No. 8, Washington, D.C., August-December, 1922.

† Several papers by W. O. Focke bearing on phenomena of self-incompatibility were published between the years 1887 and 1893.

Digitized by Google

Such excellent varieties as the Easter Lily, the Madonna Lily, Henry's Lily, the Lance-leaved Lily (L. speciosum), and the Regal Lily are readily grown from seed. Frequently blooms may be had on seedlings in two years—certainly they may be had in three years. The growing and breeding of Lilies from seed presents many interesting possibilities, not only to the commercial growers of bulbs, but to the amateur gardener as well.

In Lilies the bulb habit of growth does not in the least affect seed production. To obtain seed one must either grow self-compatible plants or grow strains that are cross-compatible. When this is done, seed in abundance may readily be obtained except in the relatively few cases of impotence from intersexes or hyoridity.

In the above summary of results noted over a term of years with twenty-eight species of Lilium in the New York Botanic Garden, Mr. A. B. Stout has observed that many species seem to be self-sterile, and as in the main the observations recorded differ markedly from those made on the same species in Britain, it may be well to enquire if climatic and cultural conditions have any bearing on the compatibility of Lilies, and, if so, to what extent.

In the New York Garden the Tiger Lily has been observed to be self-incompatible, as well as L. croceum and L. speciosum, and none of the following species has been found to be more than occasionally self-fertilising:—L. regale, L. candidum, L. Henryi, L. parvum, L. tenuifolium, L. Humboldtii, L. Kellogii, L. Willmottiae, L. longiflorum, L. auratum, L. Hansonii, L. Parryi, L. Maximowiczii and L. chalcedonicum.

Broadly, it may be said that in this country most of the Lilies of temperate regions are self-fertile to the extent of producing fruit in a reasonably sunny summer. The so-called sterility of the cultivated forms of L. candidum has long been remarked, but this form bears fruit freely in hot summers such as those of 1911 and 1921. The same thing has been noticed with L. speciosum and L. auratum (Fig. 112), which the able investigators of the New York Garden find to be self-sterile, but, curiously enough, instances of fruiting in L. auratum are far more numerous in the comparatively humid climate of Scotland than in the south. In Great Britain it is difficult to believe that L. regale is even moderately self-incompatible, still less markedly so as Mr. Stout finds it in the New York Garden; when this species was first introduced (as L. myriophyllum) solitary, uni-flowered plants found their way to isolated places, and the free production of fruit on them was remarked. In a bed of 100 adult specimens of this Lily it would be difficult in September of any but a most unfavourable year to find a single example without fully developed capsules on plants the stigmata of which had been protected from outside interference.

L. Hansonii does not normally fruit in this country, but in the two exceptionally hot summers already referred to it bore a noticeable proportion of capsules, the contents of which germinated in due course, and came true to type. L. Henryi and L. Willmottiae are prolific seed-bearers, even in unfavourable seasons, and the writer has failed to observe any difference in fecundity between caged plants and those open to fertilising insects of the day or night.

In Britain, in the ordinary course, L. parvum, L. Kellogii, L. Humboldtii, L. Parryi and L. tenuifolium show no trace of incompatibility, nor does L. chalcedonicum. Mr. Stout's observations as to the sterility of L. Batemanniae coincide with those of other observers; it seems to be a mule, but that can hardly be said of L. tigrinum, a very shy seed-bearer even in the hottest of summers.

The average New York summer is far hotter than our own, and the, to us, unusual behaviour of the Lilies in the Botanic Garden there, as recorded above by Mr. Stout, cannot be ascribed to a deficiency of sun-heat. Unless we know the conditions under which the various species are grown, it would be improper to suggest that cultivation, and possibly lack of moisture at the root in hot summers, may have some bearing on the peculiarities noticed by Mr. Stout. *A. Grove*

TREES AND SHRUBS.

CASTANEA SATIVA (VESCA) HETEROPHYLLA.

SPECIMENS, comprising foliage and fruits, of Castanea sativa heterophylla, from the Arboretum at Verrières, were exhibited at a recent meeting of the French Botanical Society. The tree in question is interesting in that it bears at the same time, on certain branches, leaves of the normal, entire, character, and on others, laciniate foliage (Fig. 113).

The tree in question is already of a fair age, and no particular attention has hitherto been paid to it, at any rate in latter years. It would appear to be a case of "chimera" comparable to a certain extent to the case of Amygdalopersica Formonti, at Montreuil, near Paris, a Peach tree bearing branches of Almond, which was described by M. Rivière (*C. R. Académie des Sciences*, 1915, page 497).

In the case of the Chestnut, a variety with laciniate leaves must have been grafted on to the type with entire foliage. All the Castaneas called heterophylla to be found in parks or nurseries, or which have been described, appear to bear foliage more or less laciniate without displaying any tendency to foliar dimorphism.

There is a variety called heterophylla dissecta, described in the *Gardeners' Chronicle* of 1872 (page 1289), which was said to have borne, at the base of the branches, laciniate, almost linear leaves, elongated, and with pendant extremities. This description agrees fairly well with the appearance of the Verrières tree and of the seedlings arising from it, if the branches of the original which bear entire leaves are ignored.

At various times, seeds of the two forms have been sown. The fruits are, moreover, distinct; on the branches with entire leaves, the spines of the fruits are a little longer, and very much thicker than on the fruits borne by the branches with laciniate foliage. All the seeds of the normal-leaved form have reproduced that form, while those of the laciniate-leaved form have yielded, in the aggregate, a little more than half the number of plants with normal leaves, and the remainder laciniate. *A. M.*

FIG. 113.—CASTANEA SATIVA (VESCA) HETEROPHYLLA.

VERONICA SALICIFOLIA.

JUDGING from the relatively small number of specimens one meets with in this part of the country Veronica salicifolia does not seem to be so much grown as it deserves to be. It is a fine, evergreen, flowering shrub which, like most of the other shrubby Veronicas, adapts itself readily to almost any kind of soil and situation in which ordinary flowering shrubs will succeed, and when it is in full bloom it is a strikingly beautiful plant. Possibly its rather unusual occurrence in this district may be due to an impression that it is not quite hardy, but this is not the case.

Both in Nicholson's *Dictionary of Gardening* (vol. iv., p. 150) and Webster's *Hardy Ornamental Flowering Trees and Shrubs* (p. 197) it is described as "half-hardy," and in his *Trees and Shrubs Hardy in the British Isles*, Mr. W. J. Bean states that "it is one of the tender sorts, only adapted for the mildest parts of Britain" (vol. ii., p. 639). Such statements are, however, wide of the mark. In a paper on "Shrubs and Climbers," read at one of the meetings of the Royal Caledonian Horticultural Society in 1922, Mr. J. M'Gran, of Coodham Gardens, near Kilmarnock, where a large collection of flowering shrubs is grown, referred to it as being "exceedingly hardy." I have grown it here for well over a dozen years, and it has not suffered any damage from frost. It came through the severe frost of November, 1919, when in some parts of southern Scotland the thermometer fell almost to zero, one of the severest snaps we have had for many years, unscathed, while old plants of some other Veronicas I possessed were completely destroyed. In fact, I have never yet seen Veronica salicifolia injured by frost, and when statements to the contrary are made, the possibility of mistakes in its identification should be kept in view.

As may be seen from its seedlings, which it produces naturally in great abundance, Veronica salicifolia is a somewhat variable plant. The variations, however, so far as my experience of it goes, are mostly in the habit of the plant and form of the foliage, some plants being more robust than others, while in some the leaves are larger and of a deeper green colour than in others. But the most striking thing is that among the seedlings two

Digitized by Google

types which are quite distinct in their habit of flowering may appear. In one of these the flowering period is, as in V. Traversii and most of the other shrubby species, confined to two or three weeks in June. In the other the flowering period extends over the rest of the season, that is, from June till late autumn, or even until the frosts appear (at this date—November 13—I have two plants which still show a few racemes of unopened flowers), which, of course, greatly adds to its value as a decorative subject. So far, I have found no variation in the colour of the flowers, which are white suffused with delicate lilac. The racemes are from five to six inches in length, and the flowers, which emit a rather powerful, honey-like fragrance, seem to be very attractive to bees of all kinds, which visit them in large numbers. *A. D. Richardson, Edinburgh.*

ARBUTUS UNEDO.

MANY complaints have been made recently concerning the failure of this beautiful shrub when planted as a bush. Its hardiness is questioned, but recent winters have not been severe. We have in these grounds a fine clump planted some twenty years ago, and now about 16 feet high, covered with berries and bloom also. The position is a very cold one, on the north-east side of a high wood and rather in the shade. There appear to be several hybrids, as variations in size of the berry, colour and setting qualities are most noticeable. Recent plantings of Arbutus have been very successful. Plenty of old mortar rubble should be worked into the soil at planting time to provide lime and ensure drainage, as the Arbutus dislikes stagnation. The roots should be kept as near the surface of the soil as possible and given a good mulch. *G. W. Stacey, Chorley Wood, Cedars.*

NOTES FROM WISLEY.

THE majority of people who visit Wisley go for the purpose of seeing and acquiring information about plants devoted to the decoration of gardens. There are, however, other activities of the Royal Horticultural Society which are developing into first-class national importance. For instance, additional land lately acquired at Wisley is to be employed by the Society in conjunction with the Ministry of Agriculture for testing varieties of hardy fruit for commercial purposes, and large numbers of fruit trees are about to be planted. These are chiefly standard varieties which will serve for comparison with new or comparatively unknown varieties.

In the case of Apples, three distinct stocks are being used, and are being propagated at Wisley. These have rooted well this year and it is probable that over 200 will be obtainable from the stool-beds.

Any new varieties selected for trial which show promise of commercial utility will be sent to certain research stations distributed over Great Britain, which are giving a part of their land to assist in these trials, and in due course reports will be made on the crops obtained and on their commercial value in particular districts.

Running through these new fruit plantations at Wisley are some wide Rose borders which were planted last winter. Taking into account the very sandy nature of the soil, the display made by these plants this year has been most satisfactory.

In the entomological department investigations are being made with regard to eelworm attacks on herbaceous Phloxes, the effect of which is to cause spindly growth accompanied by fasciation of the leaves and cracking of the stems. It has been observed that every variety which has been artificially infected with eelworm has been susceptible to attack, but that under natural conditions there is one variety which is apparently resistant, namely Phlox Antonin Mercie, with bluish-lilac flowers and a large white eye.

A new species of green fly of a bluish-green colour has been discovered at Wisley. It was found on the taproot of a plant of Dianthus plumarius, which was sent in to the gardens. This species has appeared also on one of the mossy Saxifrages.

In the Department of Mycology experiments are being carried out in connection with a new ailment affecting Sweet Peas under glass. Some diseased leaves of Sweet Peas were sent in for diagnosis and appeared to be suffering from mildew, but on closer examination it was found that the plants had been attacked by the white form of a brown mould. This disease has been transmitted to healthy plants by dusting on them the spores from infested leaves, and it is evident that it may become a quite serious pest under close conditions. This fungus has also been found on plants in the open, towards the end of the flowering period.

On the rock garden are still to be seen a few belated blooms such as those of Veronica catarractae, which are white with a purple eye, and of Veronica Lyallii with lilac petals and a crimson eye. These plants are members of a little plantation composed wholly of species of Veronica. The bright red flowers of Schizostylis coccinea, which has done very well this year, are bowed to the ground, but Ceratostigma plumbaginioides still provides a patch of blue amid its reddening foliage. Prunus Pissardii, although purple-leaved througout the year, betrays a much redder tinge towards leaf fall, and contrasts well with the yellow leaves of Clethra alnifolia.

The heavy storms have completely bared a number of trees of their leaves, but the tawny foliage of Eucryphia pinnatifolia seems remarkably persistent. The little fruits of this tree are now swelling, but will not be fully ripe until October or November of next year, when they will have attained the size and consistency of Nutmegs, and will effect the dispersal of their seeds by splitting into twelve or more pieces.

Near the foot of the rock garden is a large specimen of Abelia triflora, which has reached the height of about ten feet; after fertilisation of the flowers the ciliated sepals on top of the fruit grow larger, giving the plant a feathery look, which is reminiscent of Clematis vitalba, with its plumed carpels. *J. W. G. White.*

PRUHONICE PARK, CZECHOSLOVAKIA.

IN my note on Count Ambrôzy's evergreen garden at Malonya in *Gard. Chron.*, p. 172, I referred to another famous park of the new Czechoslovak Republic—the park of Count Ernst Silva Tarouca at Pruhonice, near Prague. This important example of landscape design is very different in style from that of the garden at Malonya.

Pruhonice is a large estate a few miles south of the Bohemian capital, and the whole park comprises not fewer than 740 acres. The ground is naturally well adapted to the development of broad landscapes, as it forms a series of continuous valleys with narrow streamlets, and ineludes two large ponds and a small lake. The soil is, for the most part, a rather fertile sandy loam. The natural forest consists of Oak (Quercus pedunculata), Linden (Tilia platyphylloe and T. parvifolia), Elms (Ulmus foliacea, hitherto known as U. campestris, and U. glabra (or montana)), Carpinus Betulus, Acer Pseudoplatanus, Betula verrucosa, as well as large areas covered with Pinus sylvestris. The wooded slopes, the wide meadows and the lakes form pretty natural scenes, and Count Silva Tarouca, who came to Pruhonice in the fall of 1886, set himself the task to develop the natural beauty of the country and to create quite a new type of landscape by planting, at least at some points, large masses of foreign Conifers and deciduous trees and shrubs, as well as different kinds of herbaceous perennials.

In some respects his work at Pruhonice may be compared with that of Prince Pückler at Muskau, Germany, who has been most successful in demonstrating the German art of landscape design. On the other hand, Pückler's well-known park that was laid out between 1815 and 1840 looks quite different, and is of a much simpler composition. Pückler contented himself with the use of the endemic trees and shrubs, while the master of Pruhonice is well acquainted with the foreign woody plants hardy in Central Europe, and tries to employ the rich dendrological material introduced from Eastern Asia and North America since the days of Thunberg and Michaux. Even the latest introductions by Wilson, Forrest and Farrer may be found in his plantations.

The first description of the park at Pruhonice, by Count Silva himself, appeared in 1909 in Part I. of the publication *Die Gartenanlagen Oesterreich-Ungarns in Wort und Bild*, edited by the then Dendrological Society of Austria-Hungary, of which he was the president. Unfortunately, the war put an end to the activities of this young society, but in 1921 a new and similar society was founded at Prague under the leadership of Count Silva and Professor Domin.

I am by no means able to give a full account of Count Silva's fine work in landscape creation. I only wish to draw the attention of readers of the *Gard. Chron.* to it. Everyone interested in landscape design who visits the older and better known parks of Bohemia, viz., Worlik or Schönhof, should not fail to pay a visit to Pruhonice. It may be reached by motor-car in about half an hour from Prague.

Count Ernst Silva Tarouca is a born landscape designer. He never had a professional adviser, and never made a plan of his park. He is his own gardener. He gained his knowledge by experience, and looks at everything with his own eyes. Being a great sportsman, too, he has that deep understanding and feeling for nature's own features which is so indispensable to anyone who tries to develop and to refine broad landscape beauty. He takes the hints given by nature itself. In choosing and arranging his plant materials he considers first the adaptability of plants for the local conditions of soil and climate. His long experiences have taught him that there are, besides our endemic plants, a good many foreign ones which he can use even with better success. Instead of the Norway Spruce, for instance, he plants the Douglas Fir, and many American Conifers show a much healthier and more rapid growth than our common European species. Abies concolor, Picea pungens, Abies arizonica, A. subalpina, Picea sitchensis and P. Engelmannii, to mention only a few examples, are thoroughly naturalised, and foreign deciduous trees, like the different red Oaks, form part of the plantations.

Naturally, the wide grounds are divided in about eight different parts, each representing a small park by itself. The new castle stands on a level with the neighbouring fields, and looks down upon a pond surrounded by large Alders, Elms and other native trees. To the east of the pond a rather steep natural rock garden rises to about fifty metres above the water. It is one of the most peculiar features of the park, formed of schistose rocks well suited to the cultivation of Alpine plants. In the course of twenty years, Count Silva has brought together quite an unique collection of almost all the Alpine plants from the northern temperate zone that are adaptable to the climatic conditions of this part of central Europe. He even partly succeeded in cultivating some rare plants of the Mediterranean mountains and the highlands of New Zealand and South America.

Owing to his long absence from his park during the war, and to the difficult situation created by it, this immense rock garden suffered much damage. Nevertheless, it still contains a great many very interesting herbaceous perennials and small shrubs growing well, in spite of the want of sufficient care. For instance, he has plants of Acaena argentea, A. Buchananii, diverse Acantholimon, many Alsine, Androsace Chamaejasme, A. foliolosa and others, Andryala Agardhii, Antennaria plantaginifolia, several Anthemis.

Digitized by Google

Artemisia Baumgartenii, A. nitida, Asperula Athoa, Aubrietias, Bergenias, Callianthemum anemonoides, a great number of fine Campanulas, Cherleria sedoides, Dianthus frigidus, D. neglectus, D. nitidus and others, Erodium Manescavii, Geranium lancastriense, various Globularia and Helianthemum, Matthiola pedemontana, Menthella corsica, Phyteumas, Potentilla alchemilloides, Primula Arctotis, P. Balbisii, P. marginata, P. pubescens, Saponaria caespitosa, a host of the rarer Saxifragas, many Sempervivums, Townsendia Wilcoxiana, Veronica aphylla, V. gentianoides and others. Among the shrubs there may be seen species of Abelia, Adenocarpus, Andromeda, Cytisus, Daphne, Escallonia, Fendlera, Hymenanthera, Gaultheria, Gaylussacia, Lithospermum, Pachystima, Phyllodoce, Salix, Santolina, and many others. There is quite a collection of Cotoneasters, representing such species from China as C. Dammeri, C. adpressa, C. Dielsiana, and a number of still unnamed forms raised from seeds I collected in 1914 in Western Yunnan, especially on the Lichiang Range. Of the genus Rhododendron, too, some very good species are growing well, viz., R. racemosum, R. poukhanense, and, of course, the well-known European species. Jasminum Beesianum ramps over the rocks as freely as in its native country. A great surprise for the dendrologist is Caesalpinia Gilliesii, and a group of Umbellularia californica also deserves special notice. Many forms of luxuriant creeping Junipers may be noted. Of the rare jewels, however, the most delicate high Alpine plants, once the most characteristic features of this giant rockery, very few have survived.

Opposite the rock garden, on the slopes west of the pond, a huge planting of hardy evergreen Rhododendrons surrounded partly by Conifers forms a striking part of the landscape. Farther to the north-west some groups of Conifers, such as Abies concolor, A. arizonica, and others are very promising for the future. On the meadow west of the castle groups of Crabapples and other pretty, flowering, small trees or big shrubs are planted. Late in the fall vigorously growing vines, like Vitis amurensis and V. Coignetiae, develop a splendid colour effect.

Further to the south, towards the end of the view from the castle, a very small pond covered with Water Lilies, and a waterfall, are surrounded by beautiful plantations of hardy perennials, early-flowering Azaleas, herbaceous Paeonies, and some rare shrubs, such as Viburnum rhytidophyllum and Hydrangea Sargentiana, as well as Lilacs, Japanese Quinces and other deciduous shrubs. The strange Pyrus Niedzwetzkyana shows its blood-red flowers and young leaves in spring, followed in the autumn by big purple fruits.

This part of the park adjacent to the castle may be regarded as a kind of pleasure ground. Farther to the south and south-west the landscape forming the real park extends for more than two miles. I cannot give a detailed account of even the more prominent parts of it. By turns the way leads over lovely meadows with picturesque groups of high trees, through more thickly wooded slopes, along shining lakes or densely vigorous plantations of Conifers or deciduous trees. One of the loveliest parts is the "deer garden," with its lake-like pond, and its long views over the winter, framed by giant Oaks, to the more distant scene, are skilfully arranged by the Count.

In a very sheltered part of the deer garden, called Hreben, a rich collection of young evergreens has been made. Besides such Conifers as Cedrus Libani (raised from seeds from the Cilician Taurus), Sequioa gigantea, Cryptomeria japonica, Libocedrus, Thujopsis, Cephalotaxus, Abies magnifica, Picea polita, Tsuga Pattoniana, and Torreya nucifera, quite a number of varieties of Ilex Aquifolium, Aucuba japonica, Berberis Julianae, B. Hookeri, Viburnum Davidii, V. rhytidophyllum, V. utile, Cotoneaster salicifolia, Lonicera pileata and L. nitida, Kalmias, Osmanthus, Pernettias, Phillyrea decora, Prunus Laurocerasus, P. lusitanica, Skimmias, Stranvaesia, Umbellularia and others seem to like the position, which is well protected against cold winds. Not far from it on a southerly, sunny slope, a collection of attractive berry-bearing shrubs is to be found. I noted among others Pyracantha coccinea and P. Gibbsii, many Cotoneasters, different Berberis, Callicarpa japonica, Euonymus species, Mahonias, Rosa species, Symphoricarpus, Symplocos and several Viburnums.

In other parts of his large park Count Silva Tarouca has made daring attempts to use masses of Conifers and deciduous trees with diversely coloured foliage, the main plants being such as Fagus sylvatica atropurpurea, Acer Schwedleri, Populus argentea, Berberis atropurpurea, Prunus Pissardii, Abies concolor, and Picea pungens. Most of these plantations are still too young to judge their real effect, but some of them are emphatically good, even in their present state of development. Here or there one might wish the artist had used those red and bluish or silvery colours to even a greater extent. The landscape scenes of this park are so extensive that often hundreds of Fagus sylvatica purpurea or Abies concolor are needed to produce the desired effect.

Every earnest scholar of modern landscape design should be thankful to Count Silva for his attempts to create natural scenes of quite distinct aspect. Nobody knows better than the artist himself how difficult such a task is. All of us who have the good fortune to study these experiments may be dead long before the true beauty of these plantations makes its appearance. It needs at least two or three generations of men to finish a great park. The best the first can do is to lay the right foundations and to prepare the grand scenes in the proper way. It is hoped that Count Silva may live long enough to do this.

I cannot close my notes on Pruhonice without mentioning the trial garden of the Dendrological Society of Prague. This society is to a certain extent the successor of the Dendrological Society of Austria-Hungary, founded in 1908. It has its garden at Pruhonice, founded in 1909, and Mr. F. Zeman, a very skilful gardener, who had been foreman in the famous Veitchian nursery at Coombe Wood, is still superintendent of the society's grounds. The Czechoslovakian Government takes a great interest in the work of the new society, and thousands of valuable trees and shrubs, as well as herbaceous perennials, are now raised in this garden for the benefit of the members of the society, that seems to prosper as well as the present circumstances will permit. The park at Pruhonice and the gardens of the society are well worth a visit by everybody interested in landscape design and dendrology.

Camillo Schneider.

VEGETABLE GARDEN.

EDIBLE LAGENARIAS.

Lagenarias having been somewhat in evidence at recent meetings of the Royal Horticultural Society, a few remarks on the value of this family for table use may be of interest to readers.

Lagenaria vulgaris edulis is a comparatively small variety; the largest and best is L. leucantha longissima, a variety which in Southern Italy produces fruits one and a half yard in length.

FIG. 114.—MESSRS. E. WEBB AND SON'S GOLD MEDAL EXHIBIT OF POTATOS AT THE NATIONAL POTATO SOCIETY'S EXHIBITION, BIRMINGHAM (SEE PAGE 314).

When these are cooked, like Vegetable Marrows, in the Italian style, they make a very acceptable dish. They should, however, be used when they are quite young, otherwise the shell becomes very hard and dry.

If the pulp of such a variety as Hercules' Club (L. clavata), which was shown at the R.H.S. meeting on October 30, is carefully extracted and the shell hung in the sun to dry it becomes very hard and lasting, and, in the hands of a modern Hercules forms a light, handy and effective weapon of offence.

The Italian name of the edible variety is Zucca di Pergola, *i.e.*, the Pergola Gourd. The name suggests the proper method of its cultivation.

In a warm summer it might be cultivated fairly successfully in the open in the South of England. *S. B. Dicks.*

BRUSSELS SPROUTS.

Plants of Brussels Sprouts should now be yielding well. All dead leaves should be kept picked off and cleared away. If the sprouts are not broken off too near the stems, fresh growths will appear in the spring, and provide a useful crop of greens, when, perhaps, other winter greens may be scarce. Do not cut the tops off the stems, as is sometimes done, as these form a protection for the sprouts;

Digitized by Google

they should be left on all the winter, and, if green vegetables are short in the early spring, they may be used then.

CHICORY.

THE Chicory is a very useful winter salad plant. The roots may now be dug up, four or five placed in an 8-inch pot filled with old potting soil, and stood in the Mushroom house or any shed from which the light can be excluded. Water the roots, and again afterwards if needed. The best produce is obtained when growth is not unduly hurried, therefore pot a few roots at a time, and allow the shoots to develop steadily.

Another way of forcing Chicory is to take up the roots, trim off the leaves about half an inch above the neck and put the roots in a dark cellar or other place where the temperature is warmer than the outside air. Alternate layers of sand or fine soil and Chicory roots are placed in position, laying the roots horizontally with the necks pointing outwards, clear of the sand or soil, so that the leaves may grow away freely.

HOT-BEDS.

IT will soon be time to prepare hot-beds for early forcing, and advantage should be taken of mild and still weather to gather material for the purpose. As soon as all the leaves of deciduous trees have fallen, they should be raked up and carted to the frame yard, ready for mixing with long stable litter. Leaves and litter combined furnish a more lasting and steadier heat than when leaves are used alone, and both should be turned over on one or two occasions before finally making the bed. When placing the material on the site of the hot-bed allow for a greater space than the frame will actually occupy, to permit of adding fresh fermenting material as a lining should it be necessary to do so to maintain sufficient warmth in the frame. *T.*

POTATO CATRIONA.

EARLY in April of this year I planted 7 lb. of Potato seed of the variety Catriona. The crop when lifted weighed 353½ lb., the nine largest tubers weighing 11 lb. *H. S. Dean, Elton Hall Gardens, near Peterborough.*

HARDY FRUIT GARDEN.

NOTABLE VARIETIES IN 1923.

IN a year when fruits have been scarce, certain sorts have cropped satisfactorily in these gardens. Of several varieties of Peaches grown in the open here, trees of Peregrine on a south-west wall ripened large, highly-coloured fruits, whilst most other varieties failed to bear. This is one of the best Peaches for growing both inside and out-of-doors. The fruits require to be gathered before they are perfectly ripe.

Nectarine Pine Apple on a south wall set an abundance of fruit which had to be severely thinned; probably the flowers of this tree escaped injury by frost, as it blossomed late. This particular Nectarine requires plenty of water at the roots. Our best Cherries were Governor Wood and Black Heart from trees on a south-east wall. Of Pears, cordon trees of Conference, Durondeau, and Beurré d'Jonghe have yielded well, and we had satisfactory crops of Plums Early Rivers, Kirke's and Victoria from trees on a south-east wall.

The best of our culinary Apples were Lane's Prince Albert (which never fails to give a good return), Potts's Seedling (the best early dessert Apple), Newton Wonder, Bismarck, Magnum Bonum, Kentish Fillbasket, and Radnor Beauty. Of dessert Apples the best cropped this year were Allington Pippin, Beauty of Bath, Lady Sudeley, James Grieve, American Mother, Ribston Pippin, Baxter's Pearmain, Sturmer Pippin, and Newtown Pippin. This last variety we have just gathered, and it keeps well until April and May; it has given a good crop from an espalier-trained tree. Utility and The Earl were our best Strawberries. Autumn Raspberries furnished a good crop *A. B. Wadds, Englefield Gardens, Reading.*

THE WOOLLY APHIS OF THE AURICULA.

IN the current number of the *Entomologist's Monthly Magazine*, there is a short description by Mr. F. Laing, M.A. (British Museum), of the species of Aphis responsible for the damage done to the roots of Auriculas. Its correct name is Geoica eragrostidis (Buckton), although for many years it has been known, in the columns of the *Gardeners' Chronicle* and in books relating to Auricula growing, as Trama auriculae, which name was given by Murray when he described this pest (*Gard. Chron.*, May 5, 1887, p. 570). Murray's description and figures clearly show that the species which he describes is not a Trama, but appears to be identical with Buckton's Geoica eragrostidis.

This short note is to point out this long-existing mistake and the importance of correctly determining these root aphides. For many years considerable confusion has existed as to the identification of members of this difficult group, but Mr. Laing has been at work on these aphides and endeavoured to sink the numerous synonyms which exist.

The Auricula root-aphis is common on the roots of grasses, e.g., Poa, and is often unwittingly introduced with soil in which plants are to be grown. A grower of Marguerites for the London markets lost a large number of his plants through the attacks of this particular species of root-aphis. Some plants had been potted in soil which had been stacked for some time in the nursery, and these grew healthily and were quite free from this pest, while other plants, potted in soil obtained directly from a pasture, were severely attacked, with the result that many died.

There appear to be two colour forms of root-aphis on the Auricula—(i) the common subterranean form, which is whitish in colour, and (ii) the form found round the "collar" of the plant, more especially in spring, which is greenish, though morphologically the same. The subterranean form lives surrounded by a woolly secretion, on the roots in little pockets of soil. The female aphis is nearly glabrous, has no cornicles or honey-tubes, and has five-jointed antennae. *G. Fox-Wilson, R.H.S. Laboratory, Wisley.*

HOME CORRESPONDENCE.

Horticulture at the British Empire Exhibition.—Quite recently I was privileged to visit the British Empire Exhibition grounds at Wembley and was surprised and delighted to see how splendidly horticultural skill is being used there. The whole conception of the Exhibition is marvellous, and the Exhibition authorities have particularly favoured horticulture. The sites secured by certain firms are, I imagine, just as good as they can be. Some of these firms are already busily engaged on their exhibits, and I understand that some prominent firms, who lacked the necessary imagination and enterprise, are now offering the more enterprising ones large sums of money to forego their positions. *Arthur McArthur.*

The Pruning of Fruit Trees.—Mr. Brotherston's interesting and instructive article on the pruning of fruit trees, p. 238, reminded me of the fact that the late Mr. J. Turner, who was for many years gardener at a large establishment in Surrey, used to employ the same method, and as a journeyman there at that time I can personally testify to the highly successful results. Whether the system would be successful in the case of trees growing in heavy, clay soil, I have not had the opportunity of testing, but on the sandy soil of that part of Surrey we never failed to obtain a good display of well developed blossoms, and later of first-class fruits. Mr. Turner started this system of pruning in the first place for the same reason as Mr. Brotherston, as the herbaceous borders were largely backed by fruit trees and were dug early to get the work forward. *W. A. Dunn, Brockwood, Alresford.*

——I agree with Mr. Brotherston in pruning fruit trees early. And, in addition, may I advance the following? By pruning early the small amount of sap still rising seals the wound, and thus, to a certain extent, prevents the entry of fungous diseases, or attacks of insects such as American Blight. If American Blight has been prevalent during the summer, some small colonies may still be found, very often on the useless shoots—that are cut away and burned. By this system of pruning the bloom buds become plump and the additional light and air ripens them. Where a garden is kept neat and trim early pruning saves labour, as not nearly the amount of sweeping up of leaves is required, and in addition the work is done more comfortably in the pleasant autumn days than later. *C. E. Bridgett.*

Apple Sops-in-Wine.—I was greatly interested in the notes on the Market Fruit Garden (p. 222), because I am partial to the Apple named Sops-in-Wine. We have a trial tree here, and it has proved a regular bearer. With all due respect to Dr. Hogg, I should not call it a vigorous growing variety, and I should keep it pruned. I had just eaten a fruit prior to reading your article, and much enjoyed the musky flavour, which is really suggestive of wine. If grown well as a dwarf tree the fruits might well be good enough for market, but I fear they would be of small size on standard trees. *Laurence J. Cook, Enfield.*

Old Scottish Plant Names.—The article on this subject by R. P. Brotherston (p. 278) interested me, but few of the names given were in use by the time I began to take notice of them in the sixties and seventies of last century. Fou for the common Houseleek was a familiar name in the north-east of Scotland; so was the Tansie, but this was applied over a wide area to Senecio Jacobaea, which was the first popular or English name that made me distrust their applicability to plants as a means to arrive at the botanical name. When dissected this Ragwort would not agree with Tanacetum at all, and I had not then seen the true Tansy. Bourtrie, for the Elder, was a well-known name, but was spelt in a variety of ways. I can add a few names that were common during the above period. Featherfoulie (fowl's feather) was the Feverfew, and Carvy, the Caraway, was evidently borrowed from the French, Italian or the Spanish *carvi*, which had other spellings in the Arabic. Grozet, Grozel and Grozert were corruptions of the French word for the Gooseberry, the last form of the word being that I have heard spoken. It is difficult to state whether Rizzar or Rizzart came directly from the French *raisin*, or from the Gaelic *raosar*, for both the Gaels and the lowland Scots borrowed names for their vocabulary. No doubt Skellach for the wild or field Mustard was borrowed from the Gaelic *sgealag*. Chucknert for Chickweed evidently was a corruption of the Saxon *cicena-wyrt*. Kale Runt and Kale Castock were both used to indicate the stem of Curled Kale in the north. Burns wrote Stock and Custoc, and his ancestors lie in Kincardineshire, where his dialect is still spoken. He used Sybow-tail for a young Onion. *J. F.*

Soil Acidity or Sourness (p. 263).—I recently saw in a field near Thurtaston Moor, Cheshire, a passable crop of Turnips amongst which Bracken was growing more or less luxuriantly as a "weed." Can *M. C. R.* explain this? Turnips on "sour" soil would be an anomaly. Is this a case of acidity favourable to the growth of Bracken but which is distinct from sourness, and therefore not unfavourable to Cruciferous crops? *E. Horton.*

Importation of Fruit Pests.—Doubtless many gardeners, faced with an abnormal shortage of dessert Pears this season, have had to purchase imported fruits to supply the dining-room. A few days ago I purchased a small quantity of expensive Californian Winter Nelis Pears. They were splendid fruits and well packed, but round the eye of nearly all, there nestled from six to ten fine, healthy specimens of mealy bug—enough to stock a garden. Such pests are easily overlooked, but it would be well if purchasers kept a look out for them. *G. W. S.*

SOCIETIES.

BIRMINGHAM CHRYSANTHEMUM.

NOVEMBER 6, 7, 8.—The combined efforts of the Birmingham Chrysanthemum and the National Potato Societies filled the whole of the floor area and part of the galleries of the huge Bingley Hall, Birmingham, with excellent displays of Chrysanthemums and other flowers, fruit, and vegetables. Although the season has been a trying one for garden produce, Chrysanthemums particularly, the big Japanese varieties were extensively and well shown, while the decorative and single-flowered sections were strongly represented.

Vegetables were much finer than usual, and the number of entries exceeded those of many previous years, but fruit was not so good or so plentiful as usual. Honorary exhibits were very numerous, as will be seen from the medal awards given below.

GROUPS.

There were three splendid groups of Japanese incurved and decorative Chrysanthemums arranged with Ferns and foliage plants. 1st, Sir GEORGE H. KENRICK, Whetstone, Edgbaston (gr. Mr. J. V. Macdonald), whose plants were artistically arranged and set off to the best advantage with graceful Bamboos and Palms, Dracaenas, Begonias, Ferns, and Nandina domestica; the 2nd award went to Alderman W. A. CADBURY, West Hills, Kings Norton (gr. Mr. H. A. Bick), whose group included some remarkably well grown and finished Japanese and incurved varieties, but the display suffered in consequence of the dearth of effective foliage plants; 3rd, JOHN ARTHUR KENRICK, Esq., Berrow Court, Edgbaston (gr. Mr. A. Cryer).

PLANTS.

For six decorative Chrysanthemums, Alderman W. A. CADBURY led with good examples of H. W. Thorpe, Cranfordia, and Lucy Lupee; 2nd, J. W. MOORE, Esq., Kings Norton (gr. Mr. F. Moorman). For three decorative Chrysanthemums, Col. A. J. PARKES, Edgbaston (gr. Mr. L. C. Hochkins) won first prize with very finely flowered specimens of Market Red, Robert Milner, and Black Hawk; 2nd, Alderman W. A. CADBURY; 3rd, Mr. E. J. KEELING, Small Heath.

Col. A. J. PARKES (gr. Mr. L. C. Hochkins) excelled in the class for six single-flowered varieties with exceptionally large, profusely flowered plants of Florrie King, Sylvia Slade, Countess of Egmont, Mary Richardson, Robert Milner, and one indifferent specimen of W. S. Smith; 2nd, Alderman W. A. CADBURY.

CUT BLOOMS.

The premier class for cut blooms required 36 distinct Japanese varieties, to be arranged in separate vases with cut foliage, for which £15 and a handsome silver challenge shield, the latter to be held for one year, were offered as first prize. The only exhibitor was Mr. H. WOOLMAN, Shirley, Birmingham, and he was awarded the first prize for a good lot of blooms, in which Dorothea Edwards, Majestic, Prince Albert, Queen Mary, Mrs. George Monro, Mrs. B. Carpenter, Golden Champion, Major Wheatley, Mrs. Algernon Davis, and Master James were of outstanding merit.

Two entries were made in the class for single-flowered varieties occupying separate flat tables 8 feet × 5 feet. Cut foliage and foliage plants were permissible, and any kind of vase could be used. Mr. H. WOOLMAN won first prize, and showed extra large and beautifully fresh blooms of Amy Thornton, Catriona, Mensa, Margaret Davis, Pink Queen, Phyllis Cooper, Hilda Shoebridge, and Joyce Strowlger; 2nd, Mr. A. H. HICKMAN, Cookley, Kidderminster.

The class for nine Japanese Chrysanthemums in three varieties, each bloom to be staged in a separate vase, brought four capital entries.—1st, The DOWAGER LADY ANNALY, Holdenby House, Northampton (gr. Mr. D. Cameron), who showed wonderfully good specimens of Shirley Golden, Victory, and Majestic (one of the last-named blooms was adjudged the best amateur's Japanese bloom in the show); 2nd, Mrs. J. B. BROOKS, Finstall Park, Bromsgrove (gr. Mr. E. Avery), with substantial blooms of Louisa Pockett, Mrs. R. C. Pulling, and Sir Edward Letchworth; 3rd, J. H. WHEATLEY, Esq., Berkswell Hall, Coventry (gr. Mr. W. H. Westbury), whose examples of William Turner were very handsome.

Mrs. J. B. BROOKS (gr. Mr. E. Avery) excelled in the class for 12 Japanese Chrysanthemums, in not fewer than 9 varieties, arranged on a table 6 feet × 3 feet. Plants and foliage were admissible. The flowers of Mrs. Algernon Davis, Mrs. R. C. Pulling, Louisa Pockett, Sir Edward Letchworth, Majestic, Helena Margerison, and Lady Talbot were of excellent quality; 2nd, Mr. W. C. ROBINSON, Coventry, whose best flowers were Mrs. W. Rigby, Mrs. J. Gibson, Majestic, and Spencer Chichester; 3rd, F. BAYLISS, Esq., Walsall (gr. Mr. C. J. White); 4th, Mrs. E. V. BUTLER, Tewkesbury (gr. Mr. A. J. Collins).

Mr. H. WOOLMAN beat six contestants in the class for three vases of a pink-coloured Japanese variety, his blooms of Mrs. B. Carpenter being noteworthy for their broad, strap-shaped, deep-pink-coloured florets; 2nd, Mr. W. C. ROBINSON, with Mrs. Algernon Davis; 3rd, Mrs. J. B. BROOKS, also with Mrs. Algernon Davis. The best three vases of a crimson-coloured Japanese variety came from W. J. GRESSON, Esq., Stoke House, Worcester (gr. Mr. T. Parry), who showed exquisitely beautiful flowers of His Majesty. Mr. W. C. ROBINSON and J. H. WHEATLEY, Esq., were placed 2nd and 3rd respectively with the variety Mrs. George Monro. The DOWAGER LADY ANNALY (gr. Mr. D. Cameron) had the winning exhibit of three vases of a white Japanese variety with shapely blooms of Mrs. G. Drabble; 2nd, J. H. WHEATLEY, Esq., with William Turner; 3rd, Mrs. J. B. BROOKS, also with William Turner.

The first prize for three vases of a yellow Japanese variety was won by Mr. E. LOWE, Coventry, who sent huge blooms of Princess Mary; 2nd, Mrs. J. B. BROOKS, with Mrs. R. C. Pulling; 3rd, J. H. WHEATLEY, Esq., also with Mrs. R. C. Pulling. There were nine good entries in the class for one vase of any variety, colour optional, other than the colours in the above classes:—1st, Mr. H. WOOLMAN, with flowers of Majestic 11 inches across; 2nd, H. F. KEEP, Esq., Edgbaston, with well-finished blooms of Fred Green.

The best of four exhibits of six varieties of single-flowered Chrysanthemums also came from Mr. H. WOOLMAN, who showed very stout-petalled blooms of Mrs. Thos. Hancock and Mrs. W. J. Godfrey, each measuring 6½ inches across. Other almost equally good varieties were Mavis (very bright), Mrs. W. Smith, Lizzie Robertson, and Catriona; 2nd, the DOWAGER LADY ANNALY, who had excellent examples of Mrs. W. J. Godfrey and Lizzie Robertson. Mr. A. H. HICKMAN was the only exhibitor in the class for six vases of decorative Chrysanthemums, and he was awarded first prize for a clean, even-sized lot of blooms. The best vase of single-flowered Chrysanthemums, arranged with any kind of foliage, was from the DOWAGER LADY ANNALY, and was much admired; 2nd, W. J. GRESSON, Esq. (gr. Mr. T. Parry); 3rd, Sir GEORGE H. KENRICK.

LOCAL CLASSES (OPEN).

Six classes were reserved for local growers, who staged a number of particularly fine blooms. The most successful exhibitors were:—H. F. KEEP, Esq. (gr. Mr. T. W. Davis), who won four first prizes; Mr. J. S. PEARSON, Erdington; and Mr. E. WINCHESTER, Rubery, who had one first prize each.

DINNER-TABLE DECORATIONS.

The two dinner-table classes decorated with (1) Chrysanthemums and (2) Chrysanthemums and other flowers were quite a feature, there being 13 and 12 entries respectively. In the first class the premier prize was won by Mr. A. W. SHIPTON, Cannon Hill Park, Birmingham, who had a dainty combination of orange and crimson coloured, single-flowered varieties arranged in gold-coloured rustic stands of medium height. Pleasing relief was afforded by the use of orange and bronze tinted Codiaeum and Berberis foliage, together with sprays of Selaginella, and green Asparagus; 2nd, W. J. GRESSON, Esq., whose tall centre-piece and smaller vases were decorated with red and yellow Chrysanthemums, small-leaved sprays of Sedum and Selaginella and Codiaeum leaves; 3rd, Mr. E. WINCHESTER, Rubery, Birmingham.

In the companion class, other flowers in addition to Chrysanthemums were required, but the receptacles were restricted to bowls and vases:—1st, W. J. GRESSON, Esq., who had low bowls decorated with Gloriosa, Francoa, single yellow Chrysanthemums, and small-flowered Orchids; the foliage employed included Codiaeum and Ampelopsis leaves and sprays of Selaginella; 2nd, Mr. A. W. SHIPTON, who relied upon a combination principally of pink Carnations, single white Chrysanthemums, and Cypripediums; 3rd, Mr. E. WINCHESTER, with red carnations and white Chrysanthemums.

SPECIAL PRIZES.

There was spirited competition in Mr. Woolman's classes for (1) nine Japanese Chrysanthemums in not fewer than six varieties:—1st, Mr. E. TOWE, Coventry, who showed meritorious flowers of William Vert, W. Rigby, Edith Cavell, Mrs. R. C. Pulling, William Turner, Princess, and Mrs. George Monro, jun.; 2nd, Mr. W. J. HUDSON, Selly Oak; 3rd, Mr. T. BLOOMER, Perry Barr. (2) Twelve Japanese blooms in four varieties:—1st, Mr. W. C. ROBINSON, Coventry, with a handsome set of flowers of Mrs. George Monro, Mrs. G. Drabble, Lloyd George, and Mrs. Algernon Davis; 2nd, Mrs. J. B. BROOKS, whose best flowers were Mrs. Algernon Davis and Mrs. R. C. Pulling. The best Japanese bloom in the show grown by an amateur was Majestic, exhibited by the DOWAGER LADY ANNALY (gr. Mr. D. Cameron), who gained the special prize of a guinea offered by Messrs. W. Wells and Co.

Mr. H. N. Ellison's prizes were offered for six exotic Ferns; 1st, Mr. E. J. KEELING, Small Heath; 2nd, JOHN ARTHUR KENRICK, Esq.

MISCELLANEOUS PLANTS.

The three entries of twelve pots of Begonia Gloire de Lorraine made a notable show: 1st, THE RT. HON. NEVILLE CHAMBERLAIN, M.P., Edgbaston (gr. Mr. P. Catt), with medium-sized plants heavily laden with flowers; 2nd, LIONEL SPIERS, Esq., Edgbaston (gr. Mr. J. Farmer), with bigger plants but not so well flowered; 3rd, Col. A. J. PARKES, Edgbaston (gr. Mr. L. C. Hochkins). For six Begonia Gloire de Lorraine, the same three exhibitors competed, but the order of merit was as follows: 1st, LIONEL SPIERS, Esq., with short, profusely flowered specimens, two feet six inches across; 2nd, Col. A. J. PARKES; 3rd, THE RT. HON. NEVILLE CHAMBERLAIN.

The best of three exhibits of twelve Cyclamens was from Mrs. O'HEA, Barford (gr. Mr. A. Shambrook), whose large plants were remarkable for their robust health, beautifully marbled foliage and strong-stemmed flowers; 2nd, Sir GEORGE H. KENRICK; 3rd, JOHN ARTHUR KENRICK, Esq. In a similar but smaller class, the same exhibitors were placed in the same order.

J. W. MOORE, Esq., King's Norton (gr. Mr. F. Moorman), excelled in the class for six pots of Salvias, with stocky, well flowered specimens; 2nd, Mrs. J. FEENEY, Berkswell (gr. Mr. W. J. Staward); 3rd, THE RT. HON. NEVILLE CHAMBERLAIN. Competition in the class for six Primula sinensis was satisfactory, but the quality of bloom was inferior to that of some years ago: 1st, J. A. KENRICK, Esq.; 2nd, H. F. KEEP, Esq.; 3rd, THE RT. HON. NEVILLE CHAMBERLAIN.

Sir GEORGE H. KENRICK beat four contestants in the next class for six Primula obconica: 2nd, J. W. MOORE, Esq. (gr. Mr. F. Moorman); 3rd, J. A. KENRICK, Esq. The last-named exhibitor took the lead in classes for (1) six single-

Digitized by Google

flowered Zonal Pelargoniums; (2) three specimen Palms; and (3) one Tree Fern, but was placed second to Sir GEORGE H. KENRICK in the class for one specimen Palm.

FRUIT.

Although there were only two entries (against four last year) in the class for a collection of British-grown fruit, staged on a table twelve feet by four feet, both displays were of excellent merit, especially the 52 dishes from Captain M. DRUMMOND, Southampton (gr. Mr. L. Smith), which included Muscat of Alexandria, Alicante and Gros Maroc Grapes, Apples, Pears, Plums and Medlars; 2nd, HUGH ANDREWS, Esq., Toddington Manor, Winchcombe (gr. Mr. J. R. Tooley), who had good Grapes, Apples, Pears, Peaches and Plums.

In the classes for single dishes of Apples, Mr. C. W. POWELL, Wareham, Hereford, was awarded first prizes for Allington Pippin, Annie Elizabeth, Cox's Orange Pippin, Charles Ross, King of the Pippins, Lane's Prince Albert and Newton Wonder. Captain M. DRUMMOND had the best specimens of Bismarck, Blenheim Orange, King of Tomkin's County and Peasgood's Nonesuch. HUGH ANDREWS, Esq., won first prize for Bramley's Seedling, and Captain R. T. HINCKES, Hereford (gr. Mr. R. Currie) showed the winning dish of Cox's Pomona. The MARQUIS OF EXETER, Stamford (gr. Mr. T. Grant), was awarded first prizes for Emperor Alexander, Gascoyne's Scarlet, The Houblon, and Warner's King. Mr. W. P. ORRILL, Hinckley, had the best examples of Lord Derby.

PEARS.

Captain M. DRUMMOND won first prizes for Beurré Diel, Catillac and Marie Louise. The MARQUIS OF EXETER was the only exhibitor of Beurré Clairgeau. F. J. J. GIBBONS, Esq., Wolverhampton (gr. F. T. Parnwell), showed the winning dish of Durondeau, and Captain R. T. HINCKES led with Doyenné du Comice.

GRAPES AND APPLES (AMATEURS).

The best three bunches of black Grapes were from HUGH ANDREWS, Esq.; 2nd, H. R. PADMORE, Esq., Edgbaston (gr. Mr. T. Batchelor); 3rd, Captain R. T. HINCKES. W. J. GRESSON, Esq., was successful in the class for three bunches of white Muscat Grapes; 2nd, Captain R. T. HINCKES; 3rd, HUGH ANDREWS, Esq. H. R. PADMORE, Esq. (gr. Mr. T. Batchelor), was the only exhibitor of two bunches of black Grapes, grown within five miles of Birmingham. For three dishes of cooking Apples the MARQUIS OF EXETER led, followed by Captain R. T. HINCKES. The last-named beat the MARQUIS OF EXETER in the class for three dishes of dessert Apples; 3rd, F. J. J. GIBBONS, Esq. Mr. C. G. COMPTON, Bournville, had the best pair of dishes of locally grown Apples; 2nd, Mr. E. J. KEELING.

VEGETABLES (OPEN).

Of the ten splendid exhibits of six dishes of Potatos, the 1st prize was won by Mr. W. WHELDON, Coventry; 2nd, Major HARCOURT WEBB, Bewdley (gr. Mr. W. Gaiger); 3rd, Mr. T. ARCHER, Harborne. Major HARCOURT WEBB showed the winning dishes of (1) nine Onions, (2) six round Beet, and (3) six Parsnips. Mr. E. WINCHESTER sent the best six long Beet. From W. J. GRESSON, Esq. came the best (1) six Carrots, (2) twenty Brussels Sprouts and (3) six round Potatos. HUGH ANDREWS, Esq. excelled with Leeks, Celery and Kidney Potatos. Mr. HEDLEY MASTERS had the best Cauliflowers, and Mr. W. WHELDON led with Cabbages. Mr. T. BIRD, Sutton Coldfield, showed splendid examples of Red Cabbages and Yellow Shallots. The best of eleven exhibits of Red Shallots came from Mr. J. JONES, Selly Oak, and Mr. A. J. CARTER contributed the finest Savoys.

Messrs. Sutton and Sons offered prizes for nine distinct kinds of vegetables: 1st, HUGH ANDREWS, Esq., who staged wonderful Onions, Leeks, Cauliflowers and Celery; 2nd, Mr. E. WINCHESTER.

Messrs. Webb and Sons' prizes were offered for six distinct kinds: 1st, Mr. E. WINCHESTER, whose Cauliflowers and Celery were particularly good; 2nd, H. W. SMITH, Esq., Stourbridge (gr. Mr. H. Davis). Competition among allotment holders for Messrs. Webb and Sons' prizes for four distinct kinds brought six entries: 1st, Mr. W. PERKS, Lye; 2nd, Mr. A. J. CARTER, Erdington; 3rd, Mr. W. WHELDON, Coventry.

Messrs. Dickson and Robinson's prizes were offered for nine distinct kinds: 1st, Mr. W. WHELDON; 2nd, W. J. GRESSON, Esq.; 3rd, Mr. W. P. ORRILL. The same firm also offered prizes for their Premier Onion: 1st, Colonel HEYWOOD LONSDALE, Market Drayton (gr. Mr. J. Mills); 2nd, Mr. W. WHELDON; 3rd, G. D. SMITH, Esq., Strensham Court (gr. Mr. W. T. Cheeseman).

HONORARY EXHIBITS.

Gold Medals were awarded to Messrs. GUNN AND SONS, Olton, for Roses and fruit; Messrs. HEWITT AND CO., Solihull, for hardy shrubs; Messrs. WATERER, SONS AND CRISP, Bagshot, for hardy shrubs; THE STUDLEY HORTICULTURAL COLLEGE, for fruit; Messrs. BAKERS, Wolverhampton, for hardy shrubs and cut flowers; Messrs. W. J. GODFREY AND SON, Exmouth, for Chrysanthemums; Messrs. HOPWOOD AND SONS, Cheltenham, for fruit; Messrs. ISAAC HOUSE AND SON, Westbury-on-Trym, for Scabious and Violets; Messrs. TOOGOOD AND SONS, Southampton, for vegetables; Miss S. S. THOMPSON, Handsworth, for Cacti; Messrs. DANIELS BROS., Norwich, for Apples; Mr. H. WOOLMAN, Shirley, for Chrysanthemums; Messrs. WEBB AND SONS, Stourbridge, for vegetables; Messrs. W. H. SIMPSON AND SONS, Edgbaston, for Chrysanthemums; Mr. H. N. ELLISON, West Bromwich, for Ferns and Cacti; Messrs. DICKSON AND ROBINSON, Manchester, for vegetables.

Silver Medals were awarded to Mr. F. G. WOOD, Ashtead, Surrey, for alpine plants; Messrs. J. R. HARVEY AND SONS, Evesham, for miscellaneous plants; Messrs. FISHERS, Birmingham, for vegetables; Mr. A. SHAMBROOK, Barford, for Cyclamen.

A Bronze Medal was awarded to Mr. A. SHEPHERD, Hollywood, for Chrysanthemums.

NATIONAL POTATO.

THE National Potato Society's contribution to the successful exhibition at Bingley Hall, Birmingham, on November 6, 7 and 8 was very satisfactory, there being a record number of exhibitors and exhibits. As a result of the very liberal prizes offered exhibitors were attracted from all parts of the British Isles, but the principal awards were taken by English growers, although a number went "over the border," as well as to Ireland and Wales.

OPEN CLASSES.

There were 95 entries in the section reserved for first early varieties, which included many tubers of great excellence. Miss M. E. BURTON, Polton, Midlothian, won first prize for May Queen; Mr. T. BOND, Cadishead, Manchester, for Epicure; Mr. C. HUGHES, Cannock, for Express; Mr. JOHN RIMMER, JUNR., Catishead, Manchester, for Duke of York; Mr. W. COLEMAN, Buckingham, for Dunnottar Castle, and for a white first early variety not provided for in the schedule.

Coimpetition in the section for second early varieties was very keen, no fewer than 230 dishes being submitted for adjudication. The strongest class was the one for Katie Glover (58 dishes) and the weakest King George (nine dishes). The Rev. C. J. KEAN, Woburn Park, Weybridge (gr., Mr. A. Basile), had the winning dishes of Katie Glover, Edinburgh Castle and Early Market. Mr. GEORGE ASHLEY, Irlam, showed the best tubers of Dargill Early, and Mr. JOHN RIMMER, JUNR., led with British Queen and Sir John Llewellyn. Mr. W. COLEMAN led with Great Scot and Arran Comrade. Mr. J. HUDSON, Leicester, was first with Ally and Mr. C. HUGHES with King George.

Among midseason and maincrop varieties W. J. GRESSON, Esq., Stoke House, Worcester (gr., Mr. T. Parry), won first prize for New Renown; Rev C. J. KEAN, with Prosperity; Mr. JOHN RIMMER, JUNR., with Up-to-Date, White City and Crusader; Mr. W. COLEMAN, with Tinwald Perfection and Rhoderic Dhu; Mr. J. HUDSON, with Arran Chief and Irish Chieftain; Mr. H. MORGAN, Nash, Tenbury Wells, with Bishop; Colonel PROBY, Elton Hall, Peterborough (gr., Mr. H. S. Dean) with Catriona; and Mr. WILLIAM MCCAUGHEY, Ballymena, Ireland, with Abundance type. Mr. W. E. JOB, Harvington, Kidderminster, led in the class for Golden Wonder, and Mr. E. WINCHESTER, Rubery, for Goldfinder. Mr. G. H. POWELL, Hewell, Redditch, had the best of 31 entries in the class for Majestic. Mr. GEORGE ASHLEY led in a class for any other maincrop variety not mentioned above with splendid tubers of Laing's Imperial.

Coloured varieties were well represented, there being 130 exhibits in the six classes. Mr. GEORGE ASHLEY took the lead with King Edward and Arran Victory. Mr. W. COLEMAN was first with Lochar and Kerr's Pink. Mr. J. HUDSON showed the best dish of a coloured Kidney not mentioned in the schedule, with Royal Purple.

COLLECTIONS.

The five open classes reserved for collections of Potatos produced 330 dishes, or an average of 66 dishes per class. Mr. J. HUDSON had the best of nine exhibits in a class for 12 dishes, distinct varieties; 2nd, Mr. W. COLEMAN; 3rd, Mr. JOHN RIMMER, JUNR. Mr. HUDSON also led for three dishes of non-immune varieties; 2nd, Mr. W. COLEMAN. W. J. GRESSON, Esq., won first prizes for (1) six dishes of non-immune varieties, (2) six dishes of immune varieties, and (3) three dishes of immune varieties. Mr. J. HUDSON was placed 2nd in the first and third classes, and bracketed equal 2nd with Mr. JOHN RIMMER, JUNR., in the second class.

In the classes reserved for allotment holders and amateur gardeners, Mr. E. WHITEHOUSE, Cannock, won first prize for three non-immune varieties, and Mr. W. EVANS, Barry, Cardiff, beat 27 contestants in the class for three immune varieties.

There was strong competition in the single dish classes, there being an average of 35 entries per class. The most successful exhibitors were Mr. W. COLEMAN, Coventry; Mr. E. ARNOLD, Shrewsbury; Mr. JOHN WATSON, Ashwell, Rutland; Mr. C. HUGHES, Cannock; Mr. W. WATSON, Halbeath, Dunfermline; and Mr. E. WHITEHOUSE, Cannock.

HONORARY EXHIBITS.

Large Gold Medals to Messrs. J. CARTER AND CO., London; Messrs. EDWARD WEBB AND SONS, Stourbridge (see Fig. 114, p. 311); and Messrs. DOBBIE AND CO., Edinburgh, and small Gold Medals to Mr. W. E. JOB, Kidderminster, and Mr. JOHN COCK.

MARLOW CHRYSANTHEMUM.

DURING 1923 Capt. Wright and his friends revived the old Marlow Chrysanthemum show, and their efforts were successful. They were, however, somewhat diffident as to the continuation of that success in 1924, and wondered whether the newly-found enthusiasm would abide. On November 7 they found their fears were groundless, for the Public Hall was far too crowded with exhibits for the comfort of visitors. Marlow is to be congratulated upon its second attempt and the prospect of continued success.

In the open class for eight vases of Japanese blooms, three blooms of one variety in each vase, the premier award was won by Mrs. HORNBY LEWIS (gr., Mr. R. Friend), who led in a strong competition and showed excellent flowers of Mrs. G. Monro, F. Joliffe, General Petain, R. C. Pulling, and Rosamund; 2rd. LADY TERRINGTON (gr., Mr. C. Berry). LADY TERRINGTON won in the open class for three Japanese blooms in one vase, with Lloyd George; 2nd, Mrs. HORNBY LEWIS, with F. Joliffe.

No fewer than six groups were staged in competition for the challenge cup presented by Mr. Cathcart, Three Gables, Marlow. These occupied one side of the hall and were touching

Digitized by Google

each other, and consequently lost something in general effect. The best group was the one from A. J. BINDER, Esq., who had excellent flowers, but somewhat formally arrayed; indeed, nearly all the competitors needed more space and a little more originality in design and arrangement; 2nd, A. R. SMITH, Esq., who also won the silver medal for the best bloom in the show with a gigantic example of Louisa Pockett; 3rd, Dr. W. H. LAMB.

LADY TERRINGTON was successful in the class for a display of cut Chrysanthemums arrayed to show the decorative value of the flowers; she had a very light exhibit in which practically all sections of the Chrysanthemum were well represented and pleasingly disposed; 2nd, H. ELKINGTON, Esq.; 3rd, Mrs. HORNBY LEWIS. Mrs. LAMB showed the best hand basket of Chrysanthemums; unfortunately in this class several competitors had baskets so filled that they were far too heavy for "hand" baskets.

The best pair of vases of Japanese blooms were those of Mrs. Drabble from Mr. J. W. JORDAN; 2nd, Mrs. HORNBY LEWIS, with R. C. Pulling and Rosamund. First prize and the challenge cup for the best dozen Japanese blooms, on boards, were won by Dr. LAMB (gr., Mr. R. Evans) with fine flowers of R. C. Pulling, Mrs. T. Lunt, Lloyd George and others; A. J. BINDER, Esq. (gr., Mr. G. Clark), was a very close second prize-winner; 3rd, Mrs. HORNBY LEWIS.

Mr. J. W. JORDAN (gr., Mr. Adams) led for six Japanese blooms, on boards; 2nd, LADY TERRINGTON; 3rd, H. ELKINGTON, Esq. Capt. H. B. WRIGHT won first prize for six vases of single varieties in a capital competition; 2nd, Mrs. HORNBY LEWIS.

The best amateurs' collection of Chrysanthemum blooms arrayed for effect was the one staged by Mr. J. H. TUCK, and it was a very pleasing effort in which single varieties figured largely; 2nd, Mr. E. GREEN.

Mr. ELKINGTON showed a capital lot of Apples and Pears, but had no competitors; his dishes of Beurré Diel and Durondeau Pears were excellent.

Mr. J. BROWN, Maidenhead, and Mr. W. T. HATCH, Cookham, arranged non-competitive exhibits of Chrysanthemums and floral designs.

HITCHIN CHRYSANTHEMUM.

THE annual show of the Hitchin Chrysanthemum Society was held in the local Town Hall on Thursday, the 8th inst. Despite the adverse season for Chrysanthemums, and crops in general, it was the unanimous opinion of those present that the blooms and vegetables were much finer than usual and quite up to pre-war standard. Sixty-nine classes were included in the schedule. The principal open class was for six vases of Japanese blooms, distinct, three blooms of a variety in each case. There were three competitors, and the silver challenge cup was awarded to Sir CHARLES NALL-CAIN, Bt. (gr., T. Pateman), for fine specimens of Wm. Rigby, Mrs. G. Drabble, Golden Champion, Mrs. Algernon Davis, Princess Mary, and Mrs. J. Gibson. E. MARTIN SMITH, Esq., Codicote Lodge, Welwyn (gr., Mr. Miller) was a good second with only three points behind the winning set; his best blooms were Majestic, Louisa Pockett, and finely coloured specimens of Mrs. Algernon Davis.

For four Japanese varieties, distinct, three blooms in each vase, another silver challenge cup was offered, and this was won by B. FRANKLIN, Esq., with splendid vases of Majestic and Mrs. Algernon Davis; 2nd, Capt. J. S. ALTON, Esq., Buntingford; 3rd, J. FLACK, Esq,. Stevenage.

For six Japanese blooms, distinct, E. MARTIN SMITH, Esq., was placed first, and he also excelled in the class for a vase of three coloured Japanese blooms, in which Sir CHARLES NALL-CAIN was second.

In the class for six varieties of singles, five blooms in a vase, E. MARTIN SMITH, Esq., was placed first in a very strong competition, Sir CHARLES NALL-CAIN being second.

In the class for the best arranged vase of singles Sir CHARLES was an easy first prize-winner. There were two classes for winter flowering Begonias, and in the class for three plants of Begonia Gloire de Lorraine Sir CHARLES NALL-CAIN was placed first, and E. MARTIN SMITH, Esq., second. For three winter Begonias other than the Lorraine type Sir CHARLES again led with well grown plants of Optima, Emita and Eclipse; 2nd, Major J. F. HARRISON, Kings Waldenbury (gr., Mr. A. J. Hartless).

Messrs. ABBISS BROS. were placed first in the class for a floral group arranged in a space of 9 ft. by 4 ft. by 6 in., effect to be the leading feature. It was a tastefully arranged group.

The bronze medal offered by *Gardening Illustrated* for the best Chrysanthemum bloom in the show was awarded to Sir CHARLES NALL-CAIN for a very fine bloom of Wm. Rigby.

The competition for a table decorated with Chrysanthemums was much below the standard generally seen at this show. In the amateurs' classes Mr. W. G. P. CLARKE, the hon. secretary, was a very successful competitor.

Fruits and vegetables are generally well shown at Hitchin. The challenge cup for a collection of fruit was won by Mr. GILLINGS, The Hoo Gardens, Kimpton, who had good Grapes and excellently coloured Apples; 2nd, Major J. F. HARRISON. For six dishes of Apples, distinct, Sir CHARLES NALL-CAIN was first and Mr. GILLINGS second. The same competitor was placed first for three dishes of Pears. In the class for Grapes Major J. F. HARRISON excelled, and also for white Grapes, in which Sir CHARLES NALL-CAIN was second. But in the class for black Grapes this order was reversed.

In the special class provided by Messrs. J. Carter and Co. for a collection of vegetables of nine kinds there were four keen competitors. Sir CHARLES NALL-CAIN won the challenge cup for the second time. Major J. F. HARRISON was second, and E. MARTIN SMITH, Esq., third.

Sir CHARLES NALL-CAIN was also placed 1st in Messrs. Sutton and Sons' class for six dishes of vegetables; 2nd, Major HARRISON. In the single dish classes for vegetables Sir CHARLES NALL-CAIN was awarded the first prize for (a) three Cauliflowers, (b) six Parsnips, and (c) six Beets. E. MARTIN-SMITH, Esq., was first for six Turnips and six Carrots, whilst Major HARRISON showed the best Onions and Leeks.

In the amateurs' classes the competition was good, and the produce in some cases nearly equal to the standard of the professional gardener's class. Among the principal exhibitors were Messrs. MUDDLE, A. BARKER, and E. G. THODY.

In the cottagers' classes Mr. S. BLAND was awarded the medal offered for the highest number of successes in this section.

ROYAL CALEDONIAN.

NOVEMBER 6.—The ordinary monthly meeting of this Society was held at 5, St. Andrew Square, Edinburgh, Mr. W. G. Pirie, vice-president, in the chair.

Dr. W. Inglis Clark, F.R.S.E., gave a lecture entitled "Flowers and their Colours," illustrated by a splendid series of lantern slides in natural colours of plants under cultivation and in their natural habitats, and of mountain and other scenery generally.

The exhibits were:—Chrysanthemums, etc., from Messrs. Dobbie and Co., Ltd. (award of merit); Alligator Pear, Mangos and Rallis Berries (Solanum xanthocarpum), from Mr. Thos. Fortune, Edinburgh; Lobelia from Mr. Alex. Innes, Edinburgh, and Veronica salicifolia in flower from Mr. A. D. Richardson, Edinburgh.

TRADE NOTE.

MR. H. N. ELLISON informs us he has purchased the entire collection of Cacti and Succulents belonging to the late Croom Johnson, Esq., of Wrexham. This is probably one of the best amateur collections in the country.

ANSWERS TO CORRESPONDENTS.

ASPARAGUS AS "FERNS": *West Shepton.* Undoubtedly plants of Asparagus plumosus should be disqualified if shown as Ferns, as they have nothing whatever to do with that family of plants.

BUMBLE BEES IN GLASSHOUSES: *R. F., Norwich.* The only effective method of preventing bumble bees from entering a glasshouse is to tack tiffany or similar material over the ventilators in such a way as will not prevent the latter from opening freely.

CATERPILLARS ATTACKING PELARGONIUMS: *V. F. P. D.* Zonal Pelargoniums are frequently attacked by caterpillars during the autumn, and in some seasons they soon ruin the plants unless the latter are examined every day, and the caterpillars picked or shaken off. The varieties King of Denmark and Decorator usually suffer badly from these pests.

CABBAGE BUTTERFLIES: *M. H. F.* When the plants are attacked by the caterpillars of the Cabbage butterfly, it is rather late to resort to remedial measures such as spraying with specifics, but hand picking the caterpillars should be followed up as closely as time will permit. Next season, if your Cabbages promise to be infested with the caterpillars, spray the plants at an early stage to kill the caterpillars as they hatch, and at the same time render the Cabbages distasteful to the butterflies. Quassia extract and paraffin emulsion are two good specifics to use, but you must be careful not to apply these insecticides if the Cabbages are to be consumed shortly afterwards. Paraffin emulsion at the rate of about two or three ounces to a gallon of water would be the best material to use when the crop is nearly ready.

CELERY DISEASED: *A. D.* Your Celery plants are affected with the disease caused by the fungus Septoria petroselina Apii. See reply to *R. F.* in *Gard. Chron.*, Nov. 3, p. 270.

CHECKING WOODY GROWTH IN FRUIT TREES: *R. J. A.* We have not heard of any process of boring the stem and injecting some preparation to check the growth of fruit trees. Possibly you are thinking of ringing the bark, which has sometimes been done to check growth and promote fruitfulness. But any system which involves wounding the stem is undesirable, owing to the risk of introducing disease. The only safe and reliable methods of steadying growth and inducing fruitfulness are (1) root-pruning, and (2) moderating the usual pruning of the head. The former is the standard method adopted in gardens. The latter is more often followed by market-growers, for whom root-pruning on a large scale would be too expensive. If pruning can be restricted to mere thinning out for a year or two, or even if the leaders are allowed to go whilst the laterals are not pruned too closely, the trees will almost invariably come into fruit-bearing, provided that they are not forced with manure.

CORIARIA TERMINALIS: *J. E. A. G.* Judging from your description of the plant, together with the imperfect name on the label, we have no hesitation in stating that your specimen is Coriaria terminalis, a native of Sikkim, and introduced to this country in 1897.

LILIUM LONGIFLORUM VAR. FORMOSUM: *J. P.* When received the bulbs should be placed, three or four together, according to size, in six-inch or seven-inch pots: they should be placed well down in the pots, as this will save adding a top-dressing. If so desired they may be placed directly in a warm house with a temperature of 60° to 65°. But if the best results are expected the plants should be placed in a cold frame or cool greenhouse until they are well rooted. They will then force more readily, and the resulting flowers will be of better quality. If the plants are to be grown for conservatory or greenhouse

Digitized by Google

decoration, the latter course is the best one to follow. For this purpose they may also be grown somewhat cooler (55° to 60°).

PROPAGATION OF DAHLIAS: *M. N.* Dahlia roots may be placed in a warm house about the middle of February; a high temperature is not desirable or necessary, 50° to 55° being sufficient. If only a small number of plants is required the roots should be placed in boxes, packed around with soil, but leaving the crowns exposed. The cuttings may either be taken with a heel, or just as ordinary cuttings, trimming them off below a joint; but such cuttings should be sturdy, not weak and drawn up in a too high temperature. The old roots, if they have a few shoots left after sufficient cuttings have been taken, may be used for planting out, after they have been hardened off.

STARWEED ON GOLF COURSES: *J. B. O.* There is some doubt about the name of the weed, because on southern golf courses Starweed is a name given to Plantago coronopus, which resembles a star when its leaves lie close to the soil, which it usually does when the grass is short as on golf greens. The mowing machine cannot cut it on closely mown, firm greens. The most effective method for removing Starweed would be to cut each plant just under the surface with an old knife. The process would be somewhat tedious if the plants are numerous. A more speedy plan would be to get a box of sulphate of ammonia with one-third of common or table salt in mixture and drop a good pinch into the centre of each plant. The sulphate of ammonia should be finely powdered, and both ingredients will be more effective if quite dry at the time of application. A dry time should be selected for doing this, when the weather is likely to remain dry for two or three days at least.

SWEET PEAS FAILING: *J. T. W.* The leaves have been eaten by some biting insect, or possibly by a small slug. The seedling plants appear to have suffered from overwatering, as the collars of the plants are bent over.

TOMATO SEED: *Anxious.* The germination power of Tomato seed would probably be higher in the case of seed ripened in July than it would in the case of seed ripened in October, but there is no good reason why October-saved seed should fail to germinate well provided it was ripened and dried properly.

WEEDS IN A LAKE: *J. Macdonald.* Neither of the two bad weeds in the lake could be destroyed with a weed-killer, because the water would dilute it too much, and some of the weed-killers would be harmful to fish. If the water is shallow it would be possible to cut up Ranunculus aquatilis with the broad end of a mattock, when it could be gathered into a boat or punt with a fork. If the water is deep both of the weeds would have a considerable length, more or less upright, and could be cut from a boat with a long pole scythe, or even the blade of one firmly fixed to a long pole. The weeds would then float and could be gathered off the water. The best time to cut them would be about the end of June or before they come into bloom. This would cripple them considerably just at a time when they have expended their resources in making new growth. Some owners of large lakes run off the water periodically and clean them out. This would be the best way to get rid of Polygonum amphibium, which has long, running, underground stems or rhizomes. This weed generally grows in patches in water, and the number of the stems being relatively few, they could be pulled out from a considerable depth, if grasped by the hand low down in the water, say during June. Seeds of the Ranunculus are liable to give future crops of the weed even when the water is run off and the mud cleared out, so that periodical cleaning is necessary.

REMARKS.—The demand generally has been variable, and although prices are relatively low, supplies have been difficult to clear. Smaller shipments of Apples from North America have resulted in an advance of a point or two in prices. English Apples are selling well; the demand for large cookers continues firm. English Cox's Orange Pippin Apples are rather scarce, and available supplies sell readily. The Grape trade is steady. Guernsey Grapes are finishing, but some good bunches are being sent from Holland and Belgium in competition with home-grown Grapes. English Tomatos are almost unsaleable unless they are of first quality, the trade preferring those from the Canary Islands. A few Cucumbers are arriving and selling readily. Forced Beans are easier in value, large quantities of Beans from Madeira being an adverse factor on prices. Guernsey growers are sending some indifferent new Potatos, which are selling badly. Forced Peas and Asparagus are moving fairly well considering the comparatively high prices ruling. Mushrooms remain steady in price and quantities are small. Green vegetables remain moderately plentiful and are reasonable in price. The conditions of the Potato trade are unchanged.

REMARKS.—Chrysanthemums still constitute the main supply in this department, although the consignments are gradually lessening. There are still many inferior grades, especially amongst the "bunch" type. Of spray white M. Julian Valet is the most plentiful. Source d'Or (bronze), Lizzie Adcock (yellow) and Baldock's Crimson (red) are the best of the coloured sorts. Pink is not a good "line" at the present time. Carnations have been more plentiful during the past week. Roses are getting dearer, especially such red sorts as Liberty and Richmond. Prices are advancing for all varieties. Lilium longiflorum has not been in such demand as in the previous week, and prices are again on the down grade. The same is true of white and pink L. lancifolium, and also Richardias (Arums). Other subjects show little change from last week. The general trade conditions were very moderate during the past week; there are no new subjects to record. Supplies of French flowers are increasing, and arriving in a more reliable condition. They consist of Acacia (Mimosa), yellow Marguerites, Narcissus Paper White, N. Soleil d'Or, Anemones, Ranunculus, single and Parma Violets, the consignments of the last are irregular and the prices fluctuate. Roses Safrano and Ulrich Brunner are arriving in small quantities, but the majority of the blooms are in an advanced condition, and there is not much demand for them at present. White Lilac is arriving from Holland in a more saleable condition, and should meet with a good demand.

GARDENING APPOINTMENTS.

Mr. W. H. Wood as Gardener to Sir CHARLES OAKLEY, Frittenden House, near Staplehurst.

Mr. J. C. Payne, previously for six years General Foreman at Park Hall Gardens, Mansfield, Nottinghamshire, as Manager at the L. M. & A. Nursery, Moorgreen, near Newthorpe, Nottingham.

Mr. C. Hanson, previously Gardener at Chipstead Place, Sevenoaks, as Gardener to the Hospital Convalescent Home, Parkwood, Swanley, Kent.

Mr. A. W. Mowl, for the last two years Gardener to R. B. BARRETT, Esq., at Skipton Castle, Yorks, as Gardener to JAMES ROLLASON, Esq., Hampton Manor, Hampton-inn-Arden, Warwickshire.

Mr. Robert Middleton, for the past three years Gardener to CLAUDE ALLEN, Esq., Kilmahew, Cardross, N.B., and previously Gardener to the DUKE OF MONTROSE, Buchanan Castle, Drymen, N.B., as Gardener to LORD COWDRAY, Paddockhurst, Crawley, Sussex.

CATALOGUES RECEIVED.

WM. WATSON AND SONS, Killiney Nurseries, Killiney, Co. Dublin.—Fruit trees; Roses.

THYNE AND SON, 8 and 10, Union Street, Dundee.—Nursery stock.

ANTHONY WATERER, Knap Hill Nursery, Woking.—Hardy trees, shrubs, Conifers, etc.

The Improvement of Home-grown Wheat.

In publishing in pamphlet form the reprint of his article on the "Improvement of Home-grown Wheat," which appeared recently in the technical journal, *Milling*, Mr. A. L. Humphries has rendered a great service to the community. Although comprised within a few pages, Mr. Humphries' observations on the subject of Wheat improvement are of great importance. A little over twenty years ago, the Home-grown Wheat Committee of the National Association of British and Irish Millers, took the initiative in a sustained attempt to improve the quality of home-grown Wheat. Happily for the success of this patriotic undertaking, Mr. Humphries devoted himself enthusiastically to its promotion, and from 1901 till the present day has spared neither time nor labour in helping to secure improvement in the Wheat grown in this country. Fortunately for the undertaking, Prof. Biffin's attention had already been directed to the subject, and simultaneously with the action taken by the Wheat Committee he began his well-known and fertile experiments in Wheat breeding. It is no disparagement to Prof. Biffin to state that the successful issue of his experiments is in no small measure due to the interest which the millers on the Committee displayed in them and to their technical knowledge of milling, which they were able to put at Prof. Biffin's disposal. The problem which faced Prof. Biffin at the outset was that of producing varieties of Wheat which should be able to compete with those which for one reason or another commanded the highest price on the British market. Merely to grow the best of foreign varieties had proved that the solution of the problem did not lie in that direction; for the qualities which gave these foreign varieties their prominent position were found to be lost to a greater or less extent when they were grown in this country. Of strong Wheats—those for which the miller is willing to pay high prices—hardly any were found to be "strong" when grown here. Red Fife has proved an exception; but, unfortunately, as Mr. Humphries points out, this variety is not a profitable one either for spring or autumn sowing in this country. The variety which Prof. Biffin sought to produce had to possess strength, like that of Red Fife, high yield, immunity from disease, and freedom from the bad habit of sprouting in the ear—a defect which in a humid climate like that of these Islands must mean serious loss to the farmer or miller. That Prof. Biffin has shown the way to Wheat improvement, and realised it, is evident to all who have grown the variety of his raising known as Yeoman. Where this variety succeeds it succeeds remarkably well, and we ourselves have seen in the present year on land, which normally yields no better than four-quarters, a crop of Yeoman which, when thrashed, gave five quarters. This variety has the milling and baking qualities of Red Fife, one of its parents. As Mr. Humphries states, it yields a lively granular flour which will stand prolonged fermentation so far as "strength" is concerned, that is, the capacity to produce large and shapely loaves. Yeoman stands mid-way between Red Fife and its other parent, Grey Browick, a variety which yields a soft, white flour good for biscuits, but unsatisfactory to the baker, because it will not stand long or severe fermentation, and because the dough has a tendency to stickiness. Thus, in the descendant of these two varieties, the undesirable qualities of each have been eliminated, and the result is a variety that yields a flour which any baker may use. It is this fact on which Mr. Humphries lays such stress, for, as he points out, by the use of flour made from Yeoman, "first-class bread may be produced from Wheat grown in England." The national importance of this fact is clearly shown by Mr. Humphries. When British Wheat is in small supply it can command a good price for use in biscuit making, for puddings, and for poultry food. But when British Wheat supplies are in excess of the requirements for these purposes, the value of home grown Wheat falls; for it is only bought for bread making, for which purpose the commonly grown varieties are not very suitable and, hence, only purchased at a low price. If, on the other hand, there is available Wheat of the Yeoman type—adequate for bread making without admixture with foreign "strong" Wheats—then in those districts of England, *i.e.*, Wiltshire, Hertfordshire and Bedfordshire, where enough Wheat is raised to meet local requirements, the local Wheat can command the price which must be paid for the best foreign Wheats. Until the advent of Yeoman, farmers in these counties were, perforce, obliged to "export" from the county fifty per cent. of their Wheat, for only fifty per cent. was used locally for bread making—the remainder being required to give quality, and for that purpose exported into the area. The fifty per cent. exported Wheat, *i.e.*, Wheat sent out of the self-supplying area, would have to bear the cost of carriage, and would then only be able to compete with the cheapest foreign Wheat. Moreover, the price realised for the fifty per cent. exported Wheat would govern the price for the fifty per cent. of the crop retained in the county for mixing with foreign "strong" Wheat. Thus Mr. Humphries reaches his all important conclusion. If home-grown Wheat can be removed from the category of kinds bought for bread making purposes only if the price be low—equal to or below that of cheap, inferior, foreign, imported varieties, and if it can be bought in the category of kinds desired, or essential for bread making, the prospects of Wheat growing in England as a commercial and economic proposition may be revolutionised. Although Yeoman has pointed the way, there remains much to do before this revolution can be consummated. No one variety of Wheat succeeds in all districts, and the immediate problem is to produce other and equally good varieties which will succeed in localities where Yeoman fails. This, however, should prove no impossible task, for the way to set about doing it has been shown by Prof. Biffin, and there should be plenty of others who can follow it, albeit painfully and slowly, to its successful end. In the meantime, everybody interested in this important subject can help to disseminate knowledge of the ascertained facts, and particularly every one who grows Wheat can give a trial to varieties of the Yeoman type and help to make their virtues known to all engaged in the supply of bread stuffs.

The Waterfall at Laeken.—Many British horticulturists who have had the pleasure of visiting the famous Royal Gardens at Laeken, near Brussels, will remember the waterfall (Fig. 117, p. 323) in the lower part of the extensive pleasure grounds. The late King Leopold took the keenest possible interest in his garden and in horticulture generally, and he fully understood the value of water in garden scenery. The waterfall is a delightful feature, and its surrounding trees, shrubs, Ferns, and other plants have for so long a time occupied this position that the whole scene is a picture of natural beauty, although, of course, the waterfall is artificially produced. The water falls from a considerable height and passes away to join the lake below. A waterfall of such size would be out of place in any but a large domain, but at Laeken it adds a pleasing feature to the charming garden in which King Albert and Queen Elizabeth of Belgium find great pleasure and rest from public duties.

Forthcoming Botanical Lecture.—Sir Jagadis Bose, Director of the Bose Institute, Calcutta, will deliver a lecture before the Royal Society of Medicine on "Assimilation and Circulation in Plants," on Thursday, December 6, at 5.30 p.m., at 1, Wimpole Street, W. The chair will be taken by the President of the Society, Sir William Hale-White.

Agriculture in the Sudan.—The Department of Agriculture of the Sudan Government is requiring a Superintendent of Agriculture. Particulars of the appointment may be obtained from the Inspecting Engineer of the Egyptian and Sudan Governments, Queen Anne's Chambers, Westminster, S.W.1.

Importation of Bulbs, etc., into Holland.—Nurserymen and exporters of bulbs, etc., are reminded that, by the terms of a decree issued by the Netherlands Government, the importation into Holland of dry bulbs, tubers, and roots of flowering plants is prohibited during the period June 1 to October 31 in each year, except under permit from the Netherlands Government and after examination by Dutch officers at the port of arrival. This prohibition does not, however, apply to consignments imported through the parcels post.

Bequest to a University. — The late Mr. William Prescott has bequeathed £20,000 to the Liverpool University to found a chair of agriculture or a chair for one or more of the following subjects, namely, the chemistry of agriculture, the cultivation of land, the care, breeding, and raising of crops, the diseases of crops, or any other subject connected with agriculture. The University is given twelve months in which to decide whether or not it can accept this gift.

Generous Gift of Plants to Southport.—For several years past M, W. H. Stansfield has taken an interest in the steadily improving parks and open spaces of Southport, and has shown that interest in a practical way by presenting suitable subjects for planting. Quite recently he offered the Southport Parks Committee no fewer than 7,570 plants and, needless to say, this offer was accepted with an expression of gratitude to Mr. Stansfield for the continued interest he takes in the development of the Southport Parks and Gardens. The following is the list of plants presented: Ailanthus glandulosa, 50; Amorpha canescens, 500; Berberis dulcis nana, 100; B. Wilsonae, 100; Caragana arborescens, 100; Cercis Siliquastrum, 50; Cupressus, 100; Colutea aborescens, 100; Kerria japonica flore pleno, 50; Cornus sanguinea, 500; Cotoneaster microphylla, 550; C. Simonsii, 50; Cydonia Maulei, 50; Cytisus alpinus, 250; C. albus, 250; C. scoparius Andreanus, 100; C. nigricans, 500; Deutzia crenata fl. p., 50; D. Lemoinii, 50; D. Bride of Chester, 25; Cassinia fulvida, 50; Exochorda grandiflora, 500; Fagus sylvatica, 500; Gypsophila paniculata, 500; Hydrangea grandiflora, 100; Philadelphus in variety, 200; Pinus Pinaster (maritima), 500; Potentilla fruticosa, 250; P. Friedrichsenii 20; P. Farreri, 100; Querqus pedunculata (Robur), 100; Rosa rubiginosa, 100; Salix babylonica, 50; Spiraea ariaefolia, 50; S. Thunbergii, 50; S. Bumalda, 100; S. japonica (callosa) rubra, 100; Tamarix pentandra (hispida aestivalis), 25; Tritoma Uvaria, 500; and Yucca filamentosa, 200.

Ancient Allotments.—Some interesting particulars are given in the *Derby Daily Express* for November 16 of the allotments instituted by the Rt. Hon. Lord Melbourne eighty years ago. They are known as the Spring Garden allotments, and were formerly called "Lord Melbourne's Potato land." In a memorandum dated March 28, 1844, headed "Conditions understood, but not expressed" in the Potato Allotment Committee's agreement, it is stated, "those of the present occupiers of Lord Melbourne's Potato land who have obtained prizes, to have first choice in new field, those who have no bad mark to have a preference, those whose allotments were in good order at last examination also to have a preference." In a formal agreement, endorsed "Demise from the Right Honourable William Lord Viscount Melbourne to certain persons of land in Melbourne intended as garden ground for the use of the poor," the first clause states that Lord Melbourne agrees to let to John Joseph Deans, Joseph Hasard, William Fox Banton, Samuel Robinson, George Draper, Thomas Haimes, James Joseph Dolman, John Gutteridge, and John Earp, all the close below Calke-road, lately in the possession of Francis Dalman, containing with one half part of the brook adjoining eight acres and 35 perches, and also all that close called Calke-road piece, lately in the possession of William Banton, containing 4 acres, 3 roods, 26 perches. To hold the said land at a yearly rental of £24, in trust and as a Committee for the accommodation and convenience of the poor or labouring inhabitants of Melbourne, and for plots of garden ground for their use subject to the rules and regulations now laid down. The agreement is signed by Frederick Francis Fox, on behalf of William Lord Viscount Melbourne. These allotments have been continuous right to the present time, though held by various successors, the present owner being Lord Walter Kerr; but last year the administration was taken out of the hands of the Committee and managed direct from the Estate Office by Mr. Thomas Pearce, estate agent.

Mr. W. B. Upjohn.—Very few men have such a fine record of continuous service in one establishment as Mr. W. B. Upjohn, who for over fifty years has had charge of the Earl of Ellesmere's gardens at Worsley Hall, Worsley. Mr. Upjohn was born at Cley, Norfolk, in May, 1843, and when fourteen years of age was apprenticed to Mr. John Monro, who was then gardener to Mrs. Oddie, of Colney House, St. Albans. Young Upjohn lived with Mr. Monro, and formed an attachment with his eldest son George (the founder of the great Covent Garden business), which lasted a life time. Eventually Mr. John Monro took over a market garden at Rabley and Mr. Upjohn went with him. Four years later he obtained a situation as journeyman at Dalkeith Gardens, under Mr. William Thomson, who took a very great interest in this keen young man from the south of England. The wages were 10/- per week; the hours from 6 a.m. to 6 p.m., and often longer. A year later he was promoted to full journeyman with a wage of 12/- per week. Mr. Upjohn speaks very highly of Mr. W. Thomson, who endeavoured to inspire all his men with a keen interest in their profession, and frequently invited answers in written papers to a list of questions calculated to develop a knowledge of the theory as well as the practice of horticulture. For

MR. W. B. UPJOHN.

seven years Mr. Upjohn remained at Dalkeith, studying hard and working in each department, eventually becoming foreman in the plant department at a time when specimen Heaths and other large plants were a feature of large gardens and at prominent exhibitions. When the Earl of Ellesmere applied to Mr. Thomson for a head gardener Mr. Upjohn was recommended, and having left Dalkeith, Mr. Thomson gave him a written character "in case it might be useful," worded as follows: "W. B. Upjohn has been with me in these gardens for seven years. I have placed some three hundred men in head situations, but in no instance have I had a man of whose moral character and professional abilities I have formed so high an opinion." When Mr. Upjohn took up his duties at Worsley Hall gardens it was with an earnest desire to live up to the high character Mr. Thomson gave him. With its ten acres of kitchen garden and about sixty acres of pleasure grounds, Mr. Upjohn's duties were not light, especially as the climate was none too kind, and it was necessary to wash the glasshouses frequently during the autumn and winter to admit light to the plants in them. Men pruning shrubs became as black as chimney sweeps. Notwithstanding the difficulties, Mr. Upjohn made Worsley Hall gardens famous, and in all his efforts received the kindest assistance and consideration from his employers, the Earl and Countess of Ellesmere. In those days, more than fifty years ago, the bothy at Worsley shared a space on the north wall, with a potting shed and tool shed. At Mr. Upjohn's suggestion a fine modern building was built, with mess room, separate cubicles for each of the eight men, sitting rooms and bath room. His own house was also made as comfortable as possible, and in it Mr. Upjohn has lived for fifty-two years, and brought up eleven children to manhood and womanhood. He considers that few men have had so much happiness as he in his domestic and business affairs, notwithstanding the great changes that have come to gardening through this long period, and despite the fact that the war and the high taxation following made it impossible to maintain the gardens at Worsley in their old-time splendour. Mr. Upjohn continues to enjoy good health, and is particularly happy when old friends and acquaintances call upon him at Worsley.

Appointments for the Ensuing Week.—Sunday, December 2: Wakefield Tulip Society's meeting. Tuesday, December 4: Sevenoaks Gardeners' Chrysanthemum Society's meeting; Royal Caledonian Horticultural Society's meeting. Wednesday, December 5: Lecture at the Royal Society of Arts, at 8 p.m., on "The Work of the Royal Botanic Gardens, Kew," by Dr. A. W. Hill; Lewes and District Horticultural Society's meeting. Thursday, December 6: Wargrave and District Gardeners' Society's meeting. Friday, December 7: Bath Gardeners' Society's show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Fruit Trees.*—The soil of the most productive part of Kent is locally called Hassock, or stone-shatter; the surface of this is a mixture of sandy loam, largely intermixed with small pieces of light coloured Kentish ragstone; it is from six inches to two feet deep on solid stone rock. This land produces great quantities of Hops, Apples, Cherries, Filberts, and likewise good Turnips, Potatos, seeds, and Corn; also much excellent Hay on old Grass lands. Fruit trees of all sorts flourish and produce abundantly; even Peach and Pear trees of the most delicate kinds grow with the greatest luxuriance, and are free from disease. To what are we to attribute such results? Not to the climate, for localities enjoying a higher degree of temperature than the neighbourhood of Maidstone do not produce such fruit. The answer thus resolves itself into the fact that the quantity and superior quality of the fruits are due to the soil, being naturally in that state best suited for their healthy growth. This fact should induce us to apply the same principles to our practice in each and every other situation. Fruit trees growing in the kind of soil just described produce short-jointed wood; when the roots are stimulated by rich manures, rampant luxuriant branches are produced; when they descend to a distance beyond the genial influences of the atmosphere, they absorb a large quantity of water which the leaves are unable to get rid of by perspiration and the inevitable result is gum, canker, and a whole host of diseases; such trees continue to grow to a late period, when the lowness of temperature and the absence of sunlight render it impossible for them to give off their superabundant water by perspiration, the only means by which all trees and plants are enabled to part with it. Trees in the above-mentioned soil grow slowly; their tissues become perfectly organised as they proceed, and are not liable to be acted upon by accumulated moisture. As the days become short, and the power of the sun declines, the motion of the fluids and the action of the cells gradually cease, when the whole system is in unison with the course of nature; in winter the roots are almost dormant, the branches are short-jointed and well ripened, and all are prepared to withstand the severity of the weather and to awaken in the spring full of life and blossom. *William Keane, Gardener to George Tomline, Esq., Orwell Park, Ipswich, Gard. Chron., November* 25, 1848.

NOTICES OF BOOKS.

Gardening in South-West Scotland.

IT is often said that the mild climate of the west coast of Scotland is due to the influence of the Gulf Stream, but in his latest book,* Sir Herbert Maxwell ascribes it less to that than to the prevailing movement of the atmosphere from S.S.W. to N.N.E. Whatever the cause, the conclusion is irresistible that there are parts of the west coast where the climatic conditions are possibly even more favourable to vegetation than they are in Cornwall, for there is an absence of the arid conditions so trying to many evergreen shrubs in a hot Cornish autumn. Poolewe and Stonefield, 200 and 80 miles north the Mull of Galloway respectively, show that the extreme south-west coast of Scotland has no monopoly of the benign climate which has enabled enthusiastic gardening owners to work such wonders at Monreith, Loch Inch, Corshwall and Logan among other places in Wigtownshire. The mind boggles at the thought of the gardening paradise the country would present now had the forbears of the present generation realised their opportunities as the author and his gardening neighbours realise them now. As in all maritime districts, raging winds are the gardener's great difficulty, and Monreith is no exception. On the eastern shore of Luce Bay, Monreith has to meet the full force of the gales which sweep up the wide mouth of the bay from the south-west. Those familiar with the country thereabouts know how sharply the exposed woods are shorn up—always in the same direction—by the winds, and how happily the gales are held at bay in Sir Herbert Maxwell's garden.

Sir Herbert's book is an intimate chronicle of his own garden; he warns his readers not to regard it as a treatise on garden craft, but rather as an attempt to indicate "certain points in the arrangement of shrubs and treatment of flower borders which are not commonly kept in view as they might be," and "an endeavour to draw attention to plants out of the ordinary." Those readers who live in less genial latitudes will read with interest not untinged with envy of many plants out of the ordinary that flourish at Monreith, such as the Australasian Eucryphia, E. Billardierii, as well as the Valdivian E. cordifolia, Robinia neomexicana, Callistemon speciosus, Lardizabala, Desfontainea, which seeds about, and Senecio Huntii, among others, and, knowing their own limitations, will not be induced by Sir Herbert's success with such tender things into giving them a trial in places where they are foredoomed to failure. Some of these beautiful shrubs flourish in the home counties, miles from the sea, but the difference between those districts and the Wigtownshire coast is the difference between death and life when there is skating on the Serpentine for a week or two. Our author has many other fine shrubs and plants in his pages to which less fortunate folk may pin their faith.

No cultural secrets are disclosed in the book, doubtless because in the soil and climate of Monreith few are practised; but as befits a true gardener, the author does not hesitate to set forth his failures as well as his successes. He has not been cultivating plants and shrubs for many years with his eyes shut, and to a natural catholicity of taste and appreciation of fine things, particularly species, there is added the record of keen observation on page after page; as, for instance, on the varying effect of frost on the bloom of different Rhododendrons, on the use and misuse of peat, the vitality of seeds, Nature's profoundly ingenious methods of assuring fertilisation in many plants—Roscoea, for example—and the ways of the verminous rabbit.

Few old gardeners will read the final chapter unmoved, for much of the delight of gardening is derived from the association of plants with friends from whose hands they have come, hands in all too many instances no longer able to perform the pleasant operation of digging up and dispatching plants to others. From cover to cover the reader is conscious of the workings of a mind acutely sensible to all that is best of colour and form in the plant world, and steeped in historical knowledge which is placed at the disposal of the reader with a felicity of expression all too rare in gardening literature. The book is generously furnished with illustrations reproduced from the author's drawings. Not all the reproductions do equal justice to Sir Herbert Maxwell's facile brush, but that is doubtless due to the limitations illustration by mechanical processes imposes on those who employ it.

* *Flowers: A Garden Note-Book*, by Rt. Hon. Sir Herbert Maxwell, Bart., F.R.S., Maclehose, Jackson & Co., 25s.

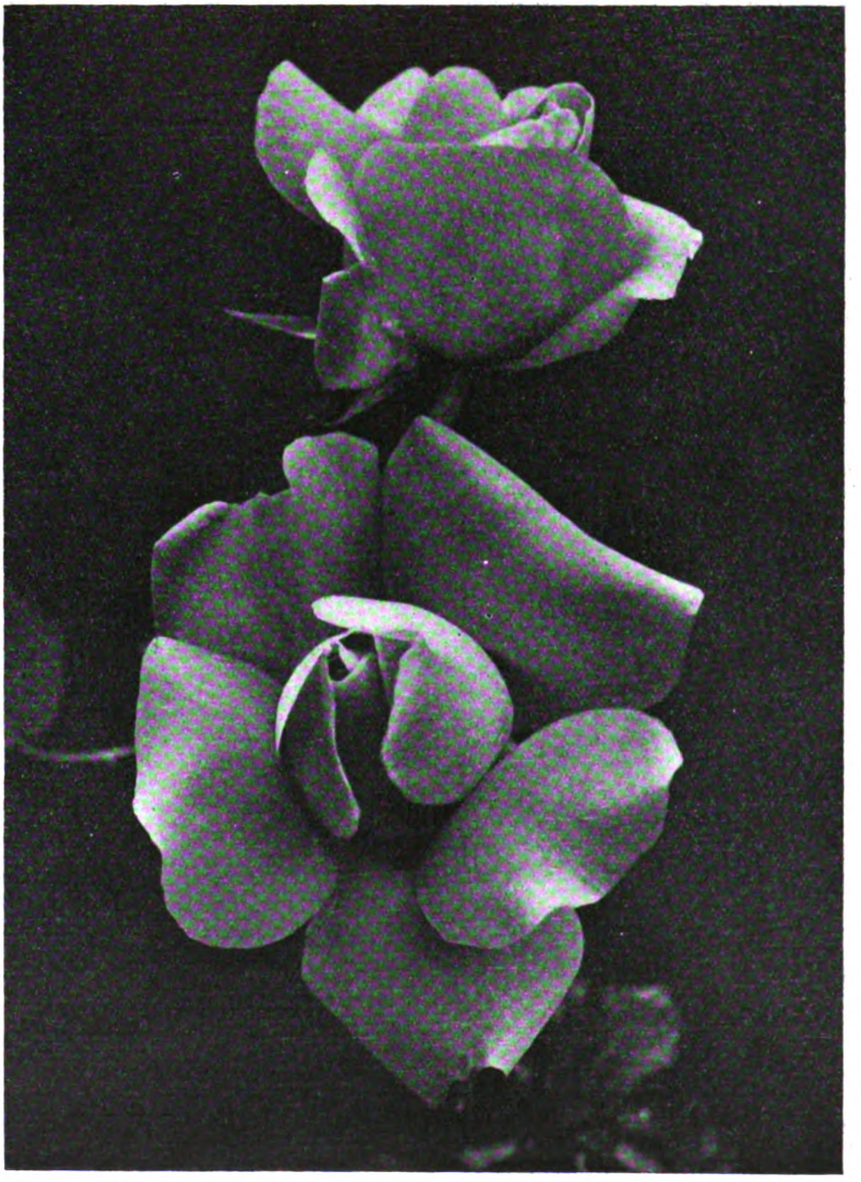

FIG. 115—ROSE FANNY OPPENHEIMER.

THE ROSE GARDEN.

ROSE FANNY OPPENHEIMER.

THIS gloriously coloured Rose (see Fig. 115) was exhibited at the autumn show of the National Rose Society on September 20 last, and surprise was expressed by many that its merits were passed over by the judges, for it was one of the most beautifully coloured Roses in the Show. It is a hybrid Tea variety, and although the buds possess good form the open blooms are rather loose and not up to the best standard so far as shape is concerned, but the variety, besides being of such a striking colour, which is best described as cardinal-red with golden-yellow at the base of the petals, has other qualities, including freedom of flowering and a robust habit. It is, however, for its colour alone that most Rose lovers will desire to possess this novelty, for the tone is nearly scarlet, and Roses of this category show to advantage in a collection.

ORCHID NOTES AND GLEANINGS.

BRASSO-CATTLEYA LADY VEZEY STRONG

A FLOWER of a new and chastely beautiful Brasso-Cattleya derived from B.-C. Digby-ano-Mendelii and C. Mrs. Percy Bigland is sent by the raiser Frederick J. Hanbury, Esq., F.L.S., Brockhurst, East Grinstead. It is large and of excellent shape, the sepals and petals being broad and well displayed, silver-white tinged with pearl pink. The showy labellum, which shows the influence of C. chocoensis in its ancestry and the distinct fringing of Brassavola Digbyana, is coloured like the petals, the disc and side lobes being Primrose yellow; the fleshy column is pure white. The Cattleya parent was a Brockhurst cross between C. chocoensis and C. Harrisoniana, which flowered there in 1913, and in the new cross with Brasso-Cattleya, the firm, wax-like texture of the lip imparted by C. Harrisoniana renders it additionally attractive.

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Trichopilia.—When well-grown, Trichopilias comprise a most interesting family of very beautiful plants. T. fragrans is, as its name implies, a sweet-scented Orchid, and is now showing its white flowers which will soon be expanded. This Orchid deserves to be grown in every collection, as spikes of deliciously scented white flowers, suitable for any kind of decoration, are not abundant at this season of the year. This plant may be grown at the warmer end of the cool house, or in any house where the winter temperature does not fall below 50°, provided a moist atmosphere is maintained. Other species of these interesting plants such as T. suavis, T. coccinea, T. tortilis, T. crispa, T. marginata, T. Backhouseana, T. laxa, and a few others, require a few degrees more heat, and a slightly drier atmosphere. The majority of these plants will have completed their growth, and should be watered with care, or their pseudo-bulbs and leaves will quickly become spotted and disfigured; over-watering at this season also causes many of the roots to decay. For so long as the pseudo-bulbs remain plump very little or no water is required, but if they show signs of shrivelling, a moderate amount of moisture should be afforded the roots. During their resting period the members of this section of Trichopilia should be placed in a cool dry part of a house, where an intermediate-house temperature is maintained. They require a light position, but not direct sunshine. The different varieties have each an individuality of their own, and the close observer will soon discern their requirements. When showing their flowers remove the plants to a shady position in a house a few degrees warmer than the one they are occupying; with more warmth the flowers will open better, and be less likely to become spotted than if left in a cooler division. There is always a danger of the flowers becoming spotted when the outside atmosphere is cold and heavily charged with moisture, if the plants are left in cool quarters. Trichopilias should be re-potted soon after growth commences, and a clean fibrous mixture similar to that used for other plants is suitable to their requirements. As healthy specimens make a considerable amount of roots, they will require plenty of pot room, whilst some of the smaller-growing species will be best accommodated in shallow pans, and grown suspended from the roof-rafters on the shady side of the house.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Wolverstone Park Gardens, Ipswich.

Successional Vineries.—When the leaves have fallen prune the vines and cleanse the rods and interior of the house. A considerable portion of the work may be done on wet days by the outdoor staff. Cleanliness is essential in the successful culture of grapes or any other kind of fruit. It is therefore advisable to undertake the work of cleansing the vines and vinery when there is the time and opportunity of carrying out the operations thoroughly. The old method of coating the vines with a mixture of clay and other ingredients obnoxious to insect pests is not to be recommended, as such mixtures are not sufficiently thin in texture to enter all the crevices. Having tried many kinds of insecticides for the destruction of scale, red spider and mealy bug on vines, I give the preference to paraffin emulsion as being the most efficacious specific for the eradication of these troublesome pests. When pruning, the wood should cut hard and clean if it is thoroughly ripened; if, on the contrary, it is soft, there is a fault somewhere which requires remedying. Overcrowding of growths or lack of other essential cultural conditions may account for the immature condition of the wood. Defective root-action is often the chief source of the trouble. Too deep a root run has an adverse influence on the quality of the wood, especially in the case of vines growing in an outside border, as the roots remain cold until quite late in the season, and the result is imperfectly ripened growth. The effect is also apparent by the irregular manner in which the vines break. There are other evils traceable to the same source; for instance, in the early stage, growth is strong for a time, but when the vines need the most assistance the root action does not progress at the same rate as top growth, owing to lack of warmth in the soil, and under such conditions the grapes set badly, generally failing to finish in good condition. To obtain Grapes of the highest excellence there should be plenty of fibrous roots near the surface, and where this is not the case the borders should be renovated and the low-lying roots brought nearer the surface. The drainage should be effectual, as anything approaching stagnant moisture in the border will have an evil effect on the roots. Outside borders should be protected from wet and cold by means of spare lights, shutters, etc.; a thick covering of leaves, overlaid with Bracken or strawy litter, forms a splendid protection.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Hippeastrums.—If these plants are required to flower early, a batch should be introduced to a warm house, plunging them, if possible, in a bed over bottom heat. A house with a temperature of 60° to 65° is suitable. The bulbs should be selected from those that were started early last year. If plants can be selected that do not require re-potting they will respond more readily to warmth when they are placed in the house. They should be well watered at the roots, after some of the top soil has been removed and substituted with a good rich compost. At the same time the bulbs should be examined for mealy bug, which often proves troublesome.

Astilbes.—These plants are very useful and popular for conservatory and greenhouse decoration. A. japonica and its varieties have long been used for this purpose; there are now numbers of pink and rose-coloured varieties which are largely grown for this purpose. Although Astilbes for forcing may be grown in gardens in moist, well-manured ground, the usual practice is to rely on purchased plants. As soon as they are received they should be placed in suitable-sized pots; although they may be grown in small receptacles, it pays to give them plenty of root room as they are strong rooting subjects and need a large amount of water when in full growth, in fact, they may at that stage be stood in shallow saucers of water. After potting the plants, they may be stood out-of-doors, plunging the pots to their rims in coal ashes, or they may be stood in cold frames until such time as it is desired to introduce them to the forcing house.

Bertolonias.—These exotic plants are grown for their beautiful marked foliage. They require a high temperature, a close, moist atmosphere, and are best grown in well-drained pans, in a compost consisting of good fibrous peat mixed with a little light loam and sufficient silver sand and charcoal to render the soil porous. Where it is difficult to maintain a close, moist atmosphere, the plants should be grown under large bell glasses. During the dull weather water should be afforded the roots with extreme care. If the shoots have grown long and leggy, the tops should be secured as cuttings, inserting them in a close propagating case, in a mixture of fibre and silver sand, in which they will root readily

Sonerila.—Like the Bertolonias, Sonerilas are usually grown for their beautifully marked foliage. They are not, however, so exacting in their cultural requirements and will grow well in a close, moist, stove temperature. Like Bertolonias they enjoy partial shade and thrive in the same kind of compost. They are best grown in small, well-drained pans. Sonerilas may be raised from seed and are also easily propagated by means of cuttings.

THE FLOWER GARDEN.

By C. TURNER, Gardener to EMILY, LADY AMPTHILL Ampthill Park, Ampthill, Bedfordshire.

Climbers.—Climbing plants are so numerous and varied that few gardens are without some representatives—the number and type of the plants depending, naturally, on available spaces or positions suitable for climbers. Just now the wild Clematis Vitalba (Traveller's Joy) is very picturesque here with its feathery seeds or fruits, masking a huge more or less dead Acacia or Locust Tree. This is the best way to grow C. Vitalba—allow it to climb up and across other trees—otherwise its truly ornamental character is not seen to the best advantage. Thus grown one need not trouble about pruning the plants, simply pulling away the dead stems as they appear in the course of time being all that is necessary. Clematis of the Jackmanni group may be pruned now in open weather or the pruning may be deferred until February. In either case hard pruning should be resorted to, cutting well back to hard wood if the plants have grown out of bounds. The strongest growing of the Rambler Roses never look better than when trained to cover the trunk of a dead tree. Roses grown in this way require attention and making secure for another season. There is no need to particularise about the pruning of these plants—they look more natural the less they are cut about, provided there is room for the growths. If not yet done Wistarias require all late and secondary growths pruned back to a promising bud and any necessary tying attended to. The Japanese Vine—Vitis Coignetiæ—needs curtailing more or less according to the size of the arbour or pergola it adorns. This plant, like the Wild Clematis, requires plenty of space over which to display its beauty, and wherever possible it should be allowed to ramble among a bush or tree, as it is in such conditions one better sees and appreciates the rich colouring of its foliage in autumn. Another excellent climber for ornamenting trees is Polygonum Baldshuanicum. It is a quick grower, quite hardy, and bears panicles of creamy-white flowers during late summer and autumn. As it is a fast grower, not the least salutary position for it is to let it roam over a large Portugal Laurel or a group of Hollies, the green foliage of the latter showing up the feathery white masses of the climber. Grown as above, pruning is not needed, but some restriction is required when the plant is grown on an ordinary pergola or pillar. Ivy growing on buildings should not be allowed to get under tiles or in guttering; therefore any shoots that have climbed up to these since the last trimming should be cut back. The Hop (Humulus Lupulus) is past its best and the vine may be cut away. All climbers I have dealt with may be now planted in suitable weather.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Rotation of Crops.—During the long winter evenings, a plan of the kitchen garden should be drawn up, and the various sites marked for next season's crops. Sheltered borders facing south will, of course, be utilised for producing the earliest crops of Peas, Potatos, French Beans, Lettuces, etc.; and these crops may be changed every alternate year. If a border is trenched one year for Peas, it will be in excellent condition for Potatos the next season—and so on. Main crop and late Peas should be grown on a fresh site every

Digitized by Google

year, allowing at least two years before they are grown on the same site again. This, however, may not always be possible in a small garden. Brassicas also should be given a fresh site every season, and the ground can scarcely be tilled too well for them. On the contrary, Onions may be grown on the same site for years, provided the ground is well prepared each season. Soils vary much, even in the same garden, and the lighter, porous land may be reserved for Carrots, Parsnips, Beets and Potatos, whilst the heavier ground may be utilised for growing Peas, Cauliflowers, Cabbages, etc.

The Use of Manures.—The texture of the soil one has to deal with will largely determine what kind of manures are most suitable. Where it can be obtained, well-rotted farmyard manure is the best to employ for most crops. For light soils cow manure is excellent, as it is more retentive of moisture than horse dung. On heavy soils it is wiser to use plenty of stable litter, rough leaves and garden refuse, as these materials tend to keep such soils open and render them easier to work as time goes on. Whatever kind of manure is used it should be well mixed with the soil, and not just thrown in haphazard. Guard against over manuring; ground which has been heavily manured one season should not be manured the next; rather apply a dressing of soot, wood ashes or lime, if it is heavy. Ground where Celery and Leeks have been grown in trenches is always in splendid condition the following season, as it is usually well manured, and also exposed to the weather. Such land is very suitable for the growing of Peas, Beans, and Potatos

The Herb Border. — All growth on Herbs should be cut down, the space between the plants lightly forked up, and a top-dressing of decayed leaves applied. A few roots of Mint may be taken up, placed in boxes of soil, and transferred to a warm house, where the plants will soon throw up plenty of fresh, green shoots. The bed may also be top dressed liberally with sifted leaf-mould.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Fruit Storage.—A constant inspection of garnered fruit should be made and the decayed examples removed. With colder days a corresponding reduction of the amount of air admitted to the fruit room should be made and the dark shutters used from now onward to preserve the late-keeping sorts as long as possible. Although direct currents of air from windows may have to be stopped, the air inlets in the walls should be opened sufficiently to maintain an even temperature and sweet atmosphere, which should be sufficiently moist. Where the floors are of stone or cement it may be advisable to damp the paths; the condition of the fruit generally should determine whether this should be done. In the early weeks after gathering, a rather higher percentage of fruit than usual seemed to decay this year.

Planting.—When fruit trees arrive from the nursery every endeavour should be made to get them planted, as weather and soil conditions permit, first seeing that water-logged soils are drained. If the ground is suitable, the trees should be planted nearly level with the surface and good soil mounded up around the roots. In all cases the soil should be made firm. Trees that do not need lifting may require a dressing of lime in some form. After the prunings are cleared away the lime may be lightly forked into the soil and if the ground has not become very cold, a mulching of manure may be applied to trees which are not over luxuriant in growth. In the case of transplanted trees which are more or less in a state of maturity, such as fully-grown cordons, a coating of manure or of decayed leaves will prevent the drying and detrimental effect of cold easterly winds.

BULB GARDEN.

SCHIZOSTYLIS COCCINEA.

THIS plant, which is also called the Kaffir Lily, was introduced from South Africa about 1864. It belongs to the Iris family, and is not so well known as its merits deserve. It flowers freely in the late autumn if the weather is mild, and is then very welcome in the garden, as the flush of flowers is over.

The growth of the plant is somewhat similar to that of the Iris, but the leaves are smaller. The flower stem grows to a height of about eighteen inches, and bears numerous open crimson flowers in the old variety, almost like a Buttercup in shape, but much larger. There is a new kind bearing pinkish blooms, but it has been introduced only lately, and is not yet in general cultivation. A great field is offered here to the plant cultivator, for new colours can doubtless be added to those we have at present. The plant is hardy in a dry and sheltered place, and can scarcely have too much sun; the secret of free flowering is in the full ripening of the growth. The plants may be obtained in the early spring, and planted at once in a light, sandy soil. It is a good plan to top-dress the plants with a little old manure after they have flowered, which will help to ward off frost, besides supplying the roots with nourishment. The plants will grow and flower well for two or three years without the need for dividing them.

Towards the end of September a few roots may be lifted carefully from the bed and potted. They will flower well under glass, but they should not be watered too freely until they are well rooted, or they may suffer. Thus treated they will afford a most acceptable attraction in a cool house and an uncommon one, or they may be placed in any warm window indoors. *T. D. T.*

CROCUS LONGIFLORUS.

THIS Crocus (see Fig. 116) has been described as the best of the autumn-flowering species and worthy of a place in every garden. It gives a display of its beautiful soft rose-coloured flowers in October and November, when most other flowers of the garden are over. The species is a native of Southern Italy, Sicily and Malta. It bears some resemblance to C. sativus, but is distinguished by its glabrous leaves and red seeds. A very fine variety of this Crocus named venustus received an Award of Merit at the meeting of the Royal Horticultural Society on October 4, 1921. The colour of this variety is bright lilac with a feathering of deep blue.

FIG. 116—CROCUS LONGIFLORUS.

ALPINE GARDEN.

THE WALNEY ISLAND GERANIUM.

CLASSED by many as a variety of Geranium sanguineum, the pretty Walney Island Geranium or Cranesbill, G. lancastriense is very distinct It is a low-growing plant not more than six inches high, and frequently less, with neat little leaves and remarkably attractive flowers of a warm rose colour veined with a deeper tone. It is one of the best rock plants in existence, and it must at the very least be reckoned as one of "the hundred best Alpines," and some would include it in a still more limited selection. It has the great merits of dwarfness, neatness and high beauty, combined with general ease of cultivation, although there seems to be some who do not succeed with it. Probably this is due to growing the plant in soil that is excessively rich. A very sandy loam or loam, peat, or leaf-mould with plenty of sand will be found quite congenial to Geranium lancastriense.

It is easily propagated by division in spring or autumn after flowering is over. This Geranium is indigenous to Walney Island, near Barrow, which is, I believe, the only place where it has been found in a wild state. It varies slightly there, I understand, but the few varieties which have been selected there are not, I believe, in cultivation. I am of the opinion that this is either a distinct species or a natural hybrid. I have alluded to difficulty being experienced by some in the cultivation of the Walney Island Cranesbill, and this is borne out by the circumstance that it is higher in price than it used to be, although this may be due to the greater demand for such a good plant. *S. Arnott.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. Barker, late Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

Trichopilia.—When well-grown, Trichopilias comprise a most interesting family of very beautiful plants. T. fragrans is, as its name implies, a sweet-scented Orchid, and is now showing its white flowers which will soon be expanded. This Orchid deserves to be grown in every collection, as spikes of deliciously scented white flowers, suitable for any kind of decoration, are not abundant at this season of the year. This plant may be grown at the warmer end of the cool house, or in any house where the winter temperature does not fall below 50°, provided a moist atmosphere is maintained. Other species of these interesting plants such as T. suavis, T. coccinea, T. tortilis, T. crispa, T. marginata, T. Backhouseana, T. laxa, and a few others, require a few degrees more heat, and a slightly drier atmosphere. The majority of these plants will have completed their growth, and should be watered with care, or their pseudo-bulbs and leaves will quickly become spotted and disfigured; over-watering at this season also causes many of the roots to decay. For so long as the pseudo-bulbs remain plump very little or no water is required, but if they show signs of shrivelling, a moderate amount of moisture should be afforded the roots. During their resting period the members of this section of Trichopilia should be placed in a cool dry part of a house, where an intermediate-house temperature is maintained. They require a light position, but not direct sunshine. The different varieties have each an individuality of their own, and the close observer will soon discern their requirements. When showing their flowers remove the plants to a shady position in a house a few degrees warmer than the one they are occupying; with more warmth the flowers will open better, and be less likely to become spotted than if left in a cooler division. There is always a danger of the flowers becoming spotted when the outside atmosphere is cold and heavily charged with moisture, if the plants are left in cool quarters. Trichopilias should be re-potted soon after growth commences, and a clean fibrous mixture similar to that used for other plants is suitable to their requirements. As healthy specimens make a considerable amount of roots, they will require plenty of pot room, whilst some of the smaller-growing species will be best accommodated in shallow pans, and grown suspended from the roof-rafters on the shady side of the house.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to J. A. Berners, Esq., Wolverstone Park Gardens, Ipswich.

Successional Vineries.—When the leaves have fallen prune the vines and cleanse the rods and interior of the house. A considerable portion of the work may be done on wet days by the outdoor staff. Cleanliness is essential in the successful culture of grapes or any other kind of fruit. It is therefore advisable to undertake the work of cleansing the vines and vinery when there is the time and opportunity of carrying out the operations thoroughly. The old method of coating the vines with a mixture of clay and other ingredients obnoxious to insect pests is not to be recommended, as such mixtures are not sufficiently thin in texture to enter all the crevices. Having tried many kinds of insecticides for the destruction of scale, red spider and mealy bug on vines, I give the preference to paraffin emulsion as being the most efficacious specific for the eradication of these troublesome pests. When pruning, the wood should cut hard and clean if it is thoroughly ripened; if, on the contrary, it is soft, there is a fault somewhere which requires remedying. Overcrowding of growths or lack of other essential cultural conditions may account for the immature condition of the wood. Defective root-action is often the chief source of the trouble. Too deep a root run has an adverse influence on the quality of the wood, especially in the case of vines growing in an outside border, as the roots remain cold until quite late in the season, and the result is imperfectly ripened growth. The effect is also apparent by the irregular manner in which the vines break. There are other evils traceable to the same source: for instance, in the early stage, growth is strong for a time, but when the vines need the most assistance the root action does not progress at the same rate as top growth, owing to lack of warmth in the soil, and under such conditions the grapes set badly, generally failing to finish in good condition. To obtain Grapes of the highest excellence there should be plenty of fibrous roots near the surface, and where this is not the case the borders should be renovated and the low-lying roots brought nearer the surface. The drainage should be effectual, as anything approaching stagnant moisture in the border will have an evil effect on the roots. Outside borders should be protected from wet and cold by means of spare lights, shutters, etc.; a thick covering of leaves, overlaid with Bracken or strawy litter, forms a splendid protection.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Hippeastrums.—If these plants are required to flower early, a batch should be introduced to a warm house, plunging them, if possible, in a bed over bottom heat. A house with a temperature of 60° to 65° is suitable. The bulbs should be selected from those that were started early last year. If plants can be selected that do not require re-potting they will respond more readily to warmth when they are placed in the house. They should be well watered at the roots, after some of the top soil has been removed and substituted with a good rich compost. At the same time the bulbs should be examined for mealy bug, which often proves troublesome.

Astilbes.—These plants are very useful and popular for conservatory and greenhouse decoration. A. japonica and its varieties have long been used for this purpose; there are now numbers of pink and rose-coloured varieties which are largely grown for this purpose. Although Astilbes for forcing may be grown in gardens in moist, well-manured ground, the usual practice is to rely on purchased plants. As soon as they are received they should be placed in suitable-sized pots; although they may be grown in small receptacles, it pays to give them plenty of root room as they are strong rooting subjects and need a large amount of water when in full growth, in fact, they may at that stage be stood in shallow saucers of water. After potting the plants, they may be stood out-of-doors, plunging the pots to their rims in coal ashes, or they may be stood in cold frames until such time as it is desired to introduce them to the forcing house.

Bertolonias.—These exotic plants are grown for their beautiful marked foliage. They require a high temperature, a close, moist atmosphere, and are best grown in well-drained pans, in a compost consisting of good fibrous peat mixed with a little light loam and sufficient silver sand and charcoal to render the soil porous. Where it is difficult to maintain a close, moist atmosphere, the plants should be grown under large bell glasses. During the dull weather water should be afforded the roots with extreme care. If the shoots have grown long and leggy, the tops should be secured as cuttings, inserting them in a close propagating case, in a mixture of fibre and silver sand, in which they will root readily

Sonerila.—Like the Bertolonias, Sonerilas are usually grown for their beautifully marked foliage. They are not, however, so exacting in their cultural requirements and will grow well in a close, moist, stove temperature. Like Bertolonias they enjoy partial shade and thrive in the same kind of compost. They are best grown in small, well-drained pans. Sonerilas may be raised from seed and are also easily propagated by means of cuttings.

THE FLOWER GARDEN.

By C. Turner, Gardener to Emily, Lady Ampthill Ampthill Park, Ampthill, Bedfordshire.

Climbers.—Climbing plants are so numerous and varied that few gardens are without some representatives—the number and type of the plants depending, naturally, on available spaces or positions suitable for climbers. Just now the wild Clematis Vitalba (Traveller's Joy) is very picturesque here with its feathery seeds or fruits, masking a huge more or less dead Acacia or Locust Tree. This is the best way to grow C. Vitalba—allow it to climb up and across other trees—otherwise its truly ornamental character is not seen to the best advantage. Thus grown one need not trouble about pruning the plants, simply pulling away the dead stems as they appear in the course of time being all that is necessary. Clematis of the Jackmanni group may be pruned now in open weather or the pruning may be deferred until February. In either case hard pruning should be resorted to, cutting well back to hard wood if the plants have grown out of bounds. The strongest growing of the Rambler Roses never look better than when trained to cover the trunk of a dead tree. Roses grown in this way require attention and making secure for another season. There is no need to particularise about the pruning of these plants—they look more natural the less they are cut about, provided there is room for the growths. If not yet done Wistarias require all late and secondary growths pruned back to a promising bud and any necessary tying attended to. The Japanese Vine—Vitis Coignetiæ—needs curtailing more or less according to the size of the arbour or pergola it adorns. This plant, like the Wild Clematis, requires plenty of space over which to display its beauty, and wherever possible it should be allowed to ramble among a bush or tree, as it is in such conditions one better sees and appreciates the rich colouring of its foliage in autumn. Another excellent climber for ornamenting trees is Polygonum Baldshuanicum. It is a quick grower, quite hardy, and bears panicles of creamy-white flowers during late summer and autumn. As it is a fast grower, not the least salutary position for it is to let it roam over a large Portugal Laurel or a group of Hollies, the green foliage of the latter showing up the feathery white masses of the climber. Grown as above, pruning is not needed, but some restriction is required when the plant is grown on an ordinary pergola or pillar. Ivy growing on buildings should not be allowed to get under tiles or in guttering; therefore any shoots that have climbed up to these since the last trimming should be cut back. The Hop (Humulus Lupulus) is past its best and the vine may be cut away. All climbers I have dealt with may be now planted in suitable weather.

THE KITCHEN GARDEN.

By R. W. Thatcher, Gardener to Mark Firth, Esq., Carlton Park, Market Harborough, Leicestershire

Rotation of Crops.—During the long winter evenings, a plan of the kitchen garden should be drawn up, and the various sites marked for next season's crops. Sheltered borders facing south will, of course, be utilised for producing the earliest crops of Peas, Potatos, French Beans, Lettuces, etc.; and these crops may be changed every alternate year. If a border is trenched one year for Peas, it will be in excellent condition for Potatos the next season—and so on. Main crop and late Peas should be grown on a fresh site every

Digitized by Google

year, allowing at least two years before they are grown on the same site again. This, however, may not always be possible in a small garden. Brassicas also should be given a fresh site every season, and the ground can scarcely be tilled too well for them. On the contrary, Onions may be grown on the same site for years, provided the ground is well prepared each season. Soils vary much, even in the same garden, and the lighter, porous land may be reserved for Carrots, Parsnips, Beets and Potatos, whilst the heavier ground may be utilised for growing Peas, Cauliflowers, Cabbages, etc.

The Use of Manures.—The texture of the soil one has to deal with will largely determine what kind of manures are most suitable. Where it can be obtained, well-rotted farmyard manure is the best to employ for most crops. For light soils cow manure is excellent, as it is more retentive of moisture than horse dung. On heavy soils it is wiser to use plenty of stable litter, rough leaves and garden refuse, as these materials tend to keep such soils open and render them easier to work as time goes on. Whatever kind of manure is used it should be well mixed with the soil, and not just thrown in haphazard. Guard against over manuring; ground which has been heavily manured one season should not be manured the next: rather apply a dressing of soot, wood ashes or lime, if it is heavy. Ground where Celery and Leeks have been grown in trenches is always in splendid condition the following season, as it is usually well manured, and also exposed to the weather. Such land is very suitable for the growing of Peas, Beans, and Potatos

The Herb Border. — All growth on Herbs should be cut down, the space between the plants lightly forked up, and a top-dressing of decayed leaves applied. A few roots of Mint may be taken up, placed in boxes of soil, and transferred to a warm house, where the plants will soon throw up plenty of fresh, green shoots. The bed may also be top dressed liberally with sifted leaf-mould.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Fruit Storage.—A constant inspection of garnered fruit should be made and the decayed examples removed. With colder days a corresponding reduction of the amount of air admitted to the fruit room should be made and the dark shutters used from now onward to preserve the late-keeping sorts as long as possible. Although direct currents of air from windows may have to be stopped, the air inlets in the walls should be opened sufficiently to maintain an even temperature and sweet atmosphere, which should be sufficiently moist. Where the floors are of stone or cement it may be advisable to damp the paths; the condition of the fruit generally should determine whether this should be done. In the early weeks after gathering, a rather higher percentage of fruit than usual seemed to decay this year.

Planting.—When fruit trees arrive from the nursery every endeavour should be made to get them planted, as weather and soil conditions permit, first seeing that water-logged soils are drained. If the ground is suitable, the trees should be planted nearly level with the surface and good soil mounded up around the roots. In all cases the soil should be made firm. Trees that do not need lifting may require a dressing of lime in some form. After the prunings are cleared away the lime may be lightly forked into the soil and if the ground has not become very cold, a mulching of manure may be applied to trees which are not over luxuriant in growth. In the case of transplanted trees which are more or less in a state of maturity, such as fully-grown cordons, a coating of manure or of decayed leaves will prevent the drying and detrimental effect of cold easterly winds.

BULB GARDEN.

SCHIZOSTYLIS COCCINEA.

THIS plant, which is also called the Kaffir Lily, was introduced from South Africa about 1864. It belongs to the Iris family, and is not so well known as its merits deserve. It flowers freely in the late autumn if the weather is mild, and is then very welcome in the garden, as the flush of flowers is over.

The growth of the plant is somewhat similar to that of the Iris, but the leaves are smaller. The flower stem grows to a height of about eighteen inches, and bears numerous open crimson flowers in the old variety, almost like a Buttercup in shape, but much larger. There is a new kind bearing pinkish blooms, but it has been introduced only lately, and is not yet in general cultivation. A great field is offered here to the plant cultivator, for new colours can doubtless be added to those we have at present. The plant is hardy in a dry and sheltered place, and can scarcely have too much sun: the secret of free flowering is in the full

FIG. 116—CROCUS LONGIFLORUS.

ripening of the growth. The plants may be obtained in the early spring, and planted at once in a light, sandy soil. It is a good plan to top-dress the plants with a little old manure after they have flowered, which will help to ward off frost, besides supplying the roots with nourishment. The plants will grow and flower well for two or three years without the need for dividing them.

Towards the end of September a few roots may be lifted carefully from the bed and potted. They will flower well under glass, but they should not be watered too freely until they are well rooted, or they may suffer. Thus treated they will afford a most acceptable attraction in a cool house and an uncommon one, or they may be placed in any warm window indoors. *T. D. T.*

CROCUS LONGIFLORUS.

THIS Crocus (see Fig. 116) has been described as the best of the autumn-flowering species and worthy of a place in every garden. It gives a display of its beautiful soft rose-coloured flowers in October and November, when most other flowers of the garden are over. The species is a native of Southern Italy, Sicily and Malta. It bears some resemblance to C. sativus, but is distinguished by its glabrous leaves and red seeds. A very fine variety of this Crocus named venustus received an Award of Merit at the meeting of the Royal Horticultural Society on October 4, 1921. The colour of this variety is bright lilac with a feathering of deep blue.

ALPINE GARDEN.

THE WALNEY ISLAND GERANIUM.

CLASSED by many as a variety of Geranium sanguineum, the pretty Walney Island Geranium or Cranesbill, G. lancastriense is very distinct It is a low-growing plant not more than six inches high, and frequently less, with neat little leaves and remarkably attractive flowers of a warm rose colour veined with a deeper tone. It is one of the best rock plants in existence, and it must at the very least be reckoned as one of "the hundred best Alpines," and some would include it in a still more limited selection. It has the great merits of dwarfness, neatness and high beauty, combined with general ease of cultivation, although there seems to be some who do not succeed with it. Probably this is due to growing the plant in soil that is excessively rich. A very sandy loam or loam, peat, or leaf-mould with plenty of sand will be found quite congenial to Geranium lancastriense.

It is easily propagated by division in spring or autumn after flowering is over. This Geranium is indigenous to Walney Island, near Barrow, which is, I believe, the only place where it has been found in a wild state. It varies slightly there, I understand, but the few varieties which have been selected there are not, I believe, in cultivation. I am of the opinion that this is either a distinct species or a natural hybrid. I have alluded to difficulty being experienced by some in the cultivation of the Walney Island Cranesbill, and this is borne out by the circumstance that it is higher in price than it used to be, although this may be due to the greater demand for such a good plant. *S. Arnott.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

MR. KINGDON WARD'S SEVENTH EXPEDITION IN ASIA.*

No. 25.—THE PLAINS AT LAST.

THE Hkamti plain is not the least astonishing feature of this queer country, Whether one approaches from north, south, east or west, to emerge suddenly from darkness on to a wide cultivated plain—it is not even a plateau—is as unexpected as it is comforting. For many days the view had been strictly rationed: or, when a glimpse was obtained over the surrounding country, one saw the same scenery repeated to the horizon in every direction—rounded hills wave beyond wave, thickly forested with the stubborn changeless green of Indo-Malayan jungle. Or, if the atmosphere was clear (a rare event) one might descry the higher ranges beyond, blue in the drenched air, rising above the high tide of forest to the snow-laden clouds. Suddenly one stepped out on to the open run of the plain; the last spurs flare away into the mist, and the whole world, as it seems, is broadcasted at one's feet.

The first-comers to Hkamti, appoaching from the Assam side a century ago, must have seen exactly the same thing. Their emotions, too, as they broke through the last rampart of uninhabited hills, and caught sight of cultivation below, must have been similar to mine. And again, when the first expeditions came up through the southern jungles from Burma, a decade ago, the leaders have told me with what joy and astonishment they burst on to the open plain.

And what is this plain?—how comes it here, itself only 1,200 feet above sea-level, though 1,200 miles from the sea as the river flows? The surrounding mountains, on the other hand, average 5,000-8,000 feet, while at the sources of the western Irrawaddy are peaks 15,000 feet high. Clearly the plain is an old lake bed. Everything points to that conclusion, including tradition. Wherever a stream exposes a section, beds of sand, gravel, and clay are seen. Fresh-water shells are found in the silt which fills the bottom lands, where paddy is grown; towards the northern end of the plain, where the "four rivers" debouch, the soil becomes more sandy. As for tradition—there is a hill on the bank of the Nam Kin, rising about a thousand feet above the level of the plain. It is crowned by a pagoda, and is known to the natives as Noi Chenam—"the hill that was submerged." At the southern end of the plain the Mali Kha, or western Irrawaddy, bursts through a gorge in the mountains; it was doubtless this river, which, cutting its way back through the encircling hills, finally drained the lake. One other point, tongues of laterite, flat-topped and steep-flanked, rising forty or fifty feet above the general level of the plain, project into the bottom land from various directions. Some of them are several miles in length, and of uniform breadth. They are evidently river terraces, left by the streams which have more easily worked their way through the alluvium of the lake bed; they roughly indicate the floor of the laket, the bottom lands having been carved out subsequently.

The plain is about forty-five miles long by ten miles broad, at its maximum, the total area being somewhere between three and four hundred square miles. About one-tenth is under cultivation.

The deglaciation of Yunnan, to which I have had occasion to refer, and the disappearance of many lakes, together with the abridgment of others (including the Hkamti lake), may all be due to one climatic cause acting over the whole region.

As might be expected, the vegetation of the plain varies widely with the nature of the soil and the amount of inundation during the rains. There are large areas covered with high grass, without a tree or a bush to vary the monotony. This is especially the condition at the south end, on the laterite platforms, and at the apex, where the soil is sandy. Very few flowers are found over this barren area, particularly in winter. A few small Compositae and a white-flowered slate-spotted Swertia are seen, besides one or two Labiate undershrubs, species of Justicia, and other insignificant Acanthaceae. But these are lost in the sea of high grass.

Thick jungle covers all the surrounding ranges, and overflows on to the plain, filling the "nullas" and fringing the river banks and sometimes the flanks of the ridges. Down in the cultivated area (where many a curious plant many be found in the Shan gardens) are wide pastures where buffaloes graze.

Finally there are the park lands—open spaces dotted over with trees and bushes, especially Citrus and Melastomaceae, the long pendent racemes of a purple-crimson Melastoma being very conspicuous.

The jungle is evergreen (though there are scattered deciduous trees, such as species of Ficus) and Indo-Malayan in composition. There are few flowers here in December. Clumps of straw-coloured Strobilanthes and species of Agapetes are met with in flower, also a few Orchids.

However, there is only a slight interruption of vegetative activity in December and January; and with the February rains, flowers begin to open. During the latter part of November I kept a temperature record, the average minimum (sheltered) for thirteen nights being 48.9° and the average maximum for eight days 71.2°, with extremes of 45° and 75°. It does not freeze on the plain, though the early morning mists which lie sometimes till ten o'clock make it feel very cold; also the snow on the surrounding hills keeps down the temperature, while in the summer the heat inside this basin is fierce. Certainly the climate is not pleasant. Biting flies of all kinds make the upper Irrawaddy jungles unpleasant to the last degree. Ague and blackwater fever are unpleasant diseases. Altogether it is not surprising the Burma Government is contemplating giving up the place.

The gardens in the Shan villages are interesting, and I derived much pleasure and instruction from wandering through them. There is good fruit, but in small quantity—Bananas, Medlars, Pumelos, and Pineapples. A little Sugar cane is also raised; on the other hand, it is impossible to obtain a single Potato, or any other respectable vegetable. A few flowers are seen—mostly aliens derived from European gardens at Myitkyina. Hedges of Lantana add a little colour to the scene, but it never seems to get out of hand, as it does further south. Another favourite shrub is a tall, untidy-looking Sunflower with bright golden blooms. Three or four species of Palm, including the graceful Sago Palm and a climbing rattan, are met with in many places; but the most surprising shrub of all was a form of Rhododendron indicum with bright carmine flowers—evidently the one seen on the Taron. (K.W. 5568). It must have been brought in from the hills, but whether as a shrub or raised from seed it is impossible to say.

Immediately after Christmas I left Hkamti, heading south for Myitkyina, distant 214 miles. But the road is fairly good.

In most respects—in its scenery, its people, even in its climate—the Hkamti country bears no more resemblance to Burma proper than does Sussex, say, to the Scotch Highlands. But, botanically, there is no break in the vegetation from Victoria Point to the sources of the western Irrawaddy, only a very gradual change; except in so far as the high ranges carry a temperate or even alpine flora southwards through the Indo-Malayan forest. Only on the upper Taron is there a real temperate flora. Our first march took us straight across the grass-covered plain to the Nam Kin. It was monotonous, for not till we were within a mile of the river did we enter the belt of jungle.

Here the reeds grew twenty feet high. But the jungle soon became as monotonous as the plain—just a wall of sombre green, striped with the ash-grey pillars of big trees. Various as the trees really are, they all look very much alike, on account of these tall, unbranched, smooth, white runks. It is quite the exception here to see a tree with rough bark, or branched low down—if the latter it is almost invariably a Ficus.

But if one looks at the tree tops, instead of at the trunks, it is a different story. The wide divergence of types is then obvious. For several days we marched through low-lying uninhabited country. Not a village or a hut did we see. Every morning we awoke in a thick clammy mist, through which the sun did not break till close on eleven o'clock. But presently, after a very gradual ascent, we found ourselves up in the hills. The early morning mist now lay below us. *F. Kingdon Ward.*

* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, 29, 1921; January 7, 21, March 11, 25, April 8, 22, May 6, 20, June 3, 17, July 1, 15, 22, August 5, 26, September 9, 23, October 7, 21, November 4, 18, December 2, 16, 30, 1922; January 13, 27, February 10, 24, March 10, 24, April 7, 21, May 5, June 2, 23, July 7, 21, August 18, September 1, 29, October 20, November 3 and 17, 1923.

THE INDIAN GARDEN IN AUTUMN.

THE month of October on the plains of India is a most interesting and busy time for the gardener and, in many respects, may be compared with April at home, except that here we are saying farewell to excessive heat, whilst at home in April it is the reverse. After October 15, the sun begins to cool down a little, and it is no longer the treacherous enemy of the European; insects and reptiles are no longer abroad but in their winter haunts; the atmosphere is genial to cool, especially after sun down, and the native gardeners, who for six months has been naked except for a loin cloth, now covers his head and shoulders with a rug.

By that time, many annuals are already in the seedling leaf in boxes and pots, while others are waiting to be sown in their flowering quarters after the removal of the hot-weather plants, such as Coleus, Cockscombs, Celosias, Zinnias, Amaranthus, and Crotons; Roses are being pruned and will flower in February—Tea Roses do especially well here—and much repotting is required to be done in the cases of Carnations, Aloysia, Liliums, Hydrangeas, Plumbago, Scabious, Violets, and a host of other useful subjects. Hedges of flowering shrubs are beginning to show colour: Lantana Camara, of which we have many hedges, is particularly bright just now with its compact orange and yellow flowers. Nerium odorum (syn. Oleander) we use extensively as a tall hedge plant as a border to Eucalyptus woods, and the plant

Digitized by Google

grows to a height of 12 to 16 feet. Its beautiful pink flowers reminds one of Rhododendron Pink Pearl when seen at a distance, but unfortunately the juice of the stem is a deadly poison and this prevents its use for purposes of cut bloom. Poinsettias are grown by the tens of thousand for the outer edgings of avenues. The plants are pruned severely every March and they make rapid, strong growth in our somewhat hungry, sandy soil, but require planting on slightly raised ground above the flooding level. Bougainvilleas of several kinds are already in flower and may be seen to the top of many forest trees. Tecoma stans, with its bunches of yellow flowers, is now at its best; this, too, is used for hedges. Plants raised from seed sown in March bear an abundance of flowers the following winter. In the fruit gardens Oranges are the next crop and are now ripening. The variety Santea is very popular here; it is a loose-skinned Orange of the Mandarin type, very sweet, and when mature, about the size of a tennis ball. Another variety which we grow extensively is Ladu, shaped like a semi-flattened ball, but delicious in flavour. Seedless Oranges are being grown, but not yet extensively. Our finest Orange trees are in the enclosed courts of the once famous Barhardinghar Ford, which was built by one of the great Mohammedan rulers. It consists of eight or more palaces, each having a square garden in its centre, a great Mohammedan Temple, and Indian village; the whole surrounded by a deep moat and gigantic wall, on the top of which is a drive 25 feet wide. The Oranges here have been noted for centuries and are much sought after.

The work in the vegetable gardens at this time is the same as that followed at home in April and March, *i.e.*, sowing and planting. The native gardeners are very interested in English vegetables, but Onions and Cauliflowers are the only two kinds they have taken to themselves, and of these many acres are grown for sale in the bazaars. Potatos are seen extensively in the Indian markets, and do remarkably well between October and March. I have just purchased some English ploughs, and am getting my carpenters and blacksmiths to make various kinds of other useful implements, such as harrows and drills. These workmen, like the Indian tailors, are very clever, and can make anything in a very short time, if given a sample or a drawing. For instance, a short time ago I had several of the best type of watering cans from home, and before they had been unpacked twenty-four hours my blacksmiths brought me one they had made from a kerosine tin; rough, of course, but exactly the same in every other respect. Our latest arrival is a motor mower, this they are very anxious to take to pieces, but Sahib has had to say no. *George Burrows, Superintendent of the State Gardens, Potiala, India.*

GARDEN NOTES FROM S.W. SCOTLAND.

IT would add materially to the autumnal beauty of British woodland if the Willow Gentian (Gentiana asclepiadea) were more frequently naturalised therein. No plant is more easily established in the floor of an open wood, at least on a soil free from lime; I do not know how it agrees with chalk or limestone. All that is necessary is to scatter the seed, which is produced in vast abundance, on places fairly bare of rank vegetation. Scrape the surface with a rake and sprinkle the seed thinly, and two years later there will appear in August and September arching sprays strung with beautiful, blue, vase-shaped flowers. Care should be taken to save seed from plants of a good colour strain—blue as nearly pure as that of G. septemfida. There are inferior varieties with muddy or ruddy-blue flowers and these should be suppressed; but the pure white variety shows in pleasing contrast with the best blue. For flower borders, the Willow Gentian is a somewhat unruly inmate, springing self-sown in places allotted to less robust plants; but in the woods one cannot have too much of it. Its root system does not lend itself readily to transplanting, except when quite small. I shall be happy to forward seed of a good strain to anyone who cares to send a stamped directed envelope.

It was a lucky chance that caused me to invest a shilling in a packet of seed of Echium plantagineum, Linn. This plant is reputed to be biennial; but, sown in the open last March and rigorously thinned out, it has flowered continuously throughout the summer and autumn months, until nipped by frost early in November. It grows about two feet high; the flowers are larger than those of Vipers' Bugloss, resembling them in opening red and turning violet-blue; they are produced in the utmost profusion, and almost everyone perambulating our garden asked for the name of "that beautiful thing." It is a native of southern Europe, spreading up the west coast so far as Jersey and reappearing near Penzance. It looks a likely plant for naturalising on barren ground near the sea, and is one of the most beautiful and common roadside weeds in Andalusia.

The same frost that finished the bloom on Echium destroyed the massive ivory panicles of Fatzia japonica, a near relative of our common Ivy, but of very different habit and appearance. When Mr. Bean was writing his admirable work on *Trees and Shrubs Hardy in the British Isles*, he was justified in describing Fatsia as bearing "about the largest leaves of any hardy evergreen"; but since that time Rhododendron sino-grande has unfurled its magnificent foliage in this country, taking the wind, so to speak, out of the sails of Fatsia.

The frost took no effect upon the flowers of Alstrœmeria pulchella (syn. psittacina), which has continued to display its quaint crimson and green blossoms since early in August, and was still quite gay on November 19th. The choicest gem of that family is A. Hookeri, which I received from the late Mr. Elwes who collected it on a high pass over the Chilian Andes. It grows only a foot high and bears most delicately tinted flowers, which harmonise admirably with its linear sea-green leaves. It is less hardy than most of the other species, indeed, Mr. Elwes grew it under glass; but it has passed through several winters here without protection.—*Herbert Maxwell, Monreith.*

FLORISTS' FLOWERS.

CHOICE EXHIBITION CHRYSANTHEMUMS.

A CLOSE scrutiny at several of the autumn Chrysanthemum shows this season revealed the most popular varieties and blooms, as staged. I have on my visits to shows made many notes which may be of assistance to intending exhibitors. Amongst varieties that have specially attracted my attention are Major Wheatley, a crushed-Strawberry coloured sport from Mrs. J. Gibson, the bloom being an exact counterpart of that excellent variety; it makes a fine "back-row" flower. Helmuth is a large Chrysanthemum of exhibition size, the colour being a rich crimson; the florets are wide and the flower is reflexed in shape and of great depth. Lord Lambourne is a handsome variety with long, twisting and incurving florets, coloured on the surface a bright chestnut-red, the underside being tinted with old gold.

The Prince is also a noble flower, coloured rich crimson-scarlet with golden-bronze reverse. It is an attractive flower of large proportions and a variety easy of culture. The shoot should be stopped in the first week of May for first crown buds. Mrs. B. Carpenter is a distinct sport from that excellent sort Mrs. Algernon Davis, the colour is a pleasing shade of deep rose and the variety is one of the best of its class. It appealed to me as one of the best winning flowers in the shows.

Ida, a deep gold-coloured variety, with the later buds showing bronzy colouration, promises to become very popular, for the bloom is of graceful appearance and of very large size, whilst the habit of growth is desirable in every respect. It makes a "back-row" flower which counts with good effect. The variety D. B. Crane produces blooms of bright scarlet colour; the flowers are of reflexing style, exquisite in form and possess broad florets. It is a striking colour and the variety is a distinct acquisition. The variety Mrs. Chas. Fox is coloured golden yellow with an orange-red flush. The blooms are of enormous size and the florets of great length, forming a most pleasing and interesting flower; it is just the sort to catch the judges' eye and command points. Major Dalgety is a well-shouldered flower of chestnut-red colour, deepening to crimson in the centre. The florets are broad and natural first crown buds produce blooms of noble size and pleasing contour. Mrs. Rupert Wilkes is one of the showiest Chrysanthemums in cultivation, the colour blendings, a beautiful golden-bronze with crimson markings, being so charming as to catch the eye at once. The flowers are of reflexing form This variety should prove useful for growing as small bush plants, the colour being in great request for table decoration. Rose Day is a Japanese incurved variety similar in tone to Rose Mrs. J. Laing; it is a flower of surpassing beauty and a telling bloom for showing either on boards or in vases. Golden Champion is truly named and a variety of great merit. Shirley Golden is an immense rich yellow variety with long, broad, reflexing florets which incurve at the tips, forming a bloom eleven inches to twelve inches deep. It makes a grand "back-row" flower for showing in vases. Victory is a well-known white variety, with long, twisting florets; the blooms are often twelve inches deep and eleven inches across.

Whilst modern progress in Chrysanthemums is largely in the direction of the decorative type, the big exhibition variety still maintains its own, and there are large numbers of enthusiasts who grow their plants mainly for the production of show blooms. The number of novelties submitted for awards this season has embraced a fair share of exhibition varieties, including Pink Pockett, a sport from the well-known Louisa Pockett; Sulphur Queen, a big, sulphur-yellow Japanese variety; Mrs. Harold Wells, a large, ivory-white variety, tinted with the palest green shade; Norman Davis, a notable addition to the big exhibition crimson varieties; and Gigantic, a charming flower of silvery-pink colouring. *G. L.*

THE IMPERIAL FORESTRY CONFERENCE OF 1923.

THE first Imperial Forestry Conference ever held in the British Empire took place in London in 1920, and originated in the idea that a stocktaking of the timber resources of the British Empire had become an urgent necessity and could only be effected by the active co-operation of the various dominions, colonies, and dependencies throughout the world. Under the leadership of Lord Lovat and others associated with him, a proposal to call together all who had a common interest in the conservation, development, and exploitation of forests throughout the British Empire became an accomplished fact. For many years previously forest policies had been left like a rudderless ship drifting on the surface of an unchartered sea. Governments and State Departments, assuming that they recognised forestry as a vital feature of rural economy in any way, were quite uncertain how far they should go in accepting a responsibility which the older States of Europe had taken upon themselves centuries before.

Apart from the British Isles, the forest possessions of the Empire exist in regions and latitudes influenced by every form of climate, degree of civilisation, and stage of economic development which could possibly be found. From the Arctic Circle to the Equator, from Colonial ambition to primeval apathy and fatalism, and from newly created industrial or mining districts to virgin bush and jungle, the custodians of Empire resources find themselves faced with problems which are continually changing in extent and complexity in whatever direction they turn. Forest Departments were formed one time or another in most British possessions, from the dominions to the dependencies, but few had any clear notion as to what they meant, nor had forest officials themselves the opportunity to initiate policies or the power to carry them out. When reforms were needed or action became desirable in any particular direction, the forest official usually found himself confronted with a higher personage or department whose sole object was to avoid friction or trouble at any cost. The preservation or improvement of a few thousand acres of forest was, in the opinion of most directors of State policy, a small matter compared with the profits from a timber concession, or the gratifying of some native village by additional grazing or fuel privileges. In short, the forest policy in most parts of the Empire was that of taking the line of least resistance, paying the salaries of a few officials, and issuing reports which demonstrated the existence of vast activities on a microscopic scale. These forest policies had nebulous objectives and indefinite aspirations, and, therefore, formed no effective barrier to the onrush of forest destruction, which has been going on for thousands of years, and can only be stopped by organised opposition on the part of the State.

Under the conditions outlined above it may easily be understood how difficult steady progress in forest development has been, whether this was concerned with the preservation of indigenous woodland or the afforestation of waste land. In the British Isles Commissions and Committees have time after time prepared schemes at the invitation of various Governments, but it was not until the European War forced the timber-using public to realise their dependence upon outside sources of supply that anything substantial was done. Any method which could crystallize ideas on forestry problems and concentrate the energies of State Departments along definite channels could not but prove of immense value, and the inauguration of conferences to be held periodically in different parts of the Empire will probably lead to far-reaching results. Conferences of this kind call attention to the increasing necessity for making the most of the earth's surface as population increases. While thinly populated countries may have a large proportion of natural forests, and be under little necessity for actual afforestation, the yield of timber per acre is invariably low, and sylviculture is impossible through lack of supervision and control. Exploitation is usually considered of more importance than conservation, and not until supplies begin to decrease does public opinion take any interest in the matter. The older and more thickly populated countries have now realised the importance of forestry, and are attempting to make good losses incurred before the value of timber was fully realised.

The above facts were kept clearly before the Forestry Conference of 1920, and a number of resolutions were passed which indicate the scope and nature of the discussions taking place. These resolutions were briefly as follow:—

(1) That each of the Governments of the Empire should lay down a definite forest policy to be administered by a properly constituted and adequate forest service.
(2) That a survey of the existing forest areas should be made and their capability to maintain an adequate supply of timber investigated.
(3) That the forest policy of every Government should be defined in a Forestry Act or Ordinance; that land should be reserved for timber production; that the Forest Authority should be assured of sufficient funds for carrying out the policy adopted: and, that officers should be appointed with the necessary training and status required by the nature of the work.
(4) That the Forest Authority should keep in close touch with timber industries.
(5) That methods of education and publicity should be encouraged for furthering the interests of the forest policy.
(6) That tree planting should be encouraged by the distribution of plants at cost price raised either in Government or private nurseries

Other resolutions dealt with research, education, and the setting up of forestry bureaux, and a final resolution recommended that the next Conference should be held in 1923 and take place in Canada.

The above is a brief history of the events which led up to the Conference in 1923 being held in Ottawa, and it is interesting to note how far the resolutions referred to above have been followed by results in the course of three years. At the opening meeting held in Ottawa on the July 25, reports were handed in from the United Kingdom, Australia, India, Irish Free State, New Zealand, South Africa, Canada, and many other Crown colonies, and marked progress was announced in certain directions, especially as regards forest policy, survey of resources, and constitution and status. Matters affecting education and the setting up of forest bureaux had not advanced owing to financial difficulties, but this could hardly have been otherwise in view of the general situation.

The 1923 Conference devoted a large share of its proceedings to the question of softwood supplies, a question very largely affecting the country in which the Conference was being held. The importance of this question to the United States was also emphasised by Colonel Graves who read a paper by Colonel Greeley in which it was shown that the annual cut in the United States was now greatly in excess of the increment. Papers were also presented setting out the approximate coniferous supply in the various parts of Europe, and showing generally that the consumption was getting ahead of the increment in practically every country, with the exception of one or two of limited importance.

Another question to which much time was devoted was the forest fire problem, from which Canada probably suffers more than any other part of the world. While it was considered that these fires could not be altogether prevented, the conclusion was arrived at that public support obtained by education and publicity in fire control, combined with more modern sylvicultural methods, would go a long way towards curing this evil.

Various other matters of minor importance were discussed. *A. E. Forbes.*

TREES AND SHRUBS.

EUONYMUS EUROPAEUS.

EUONYMUS EUROPAEUS (Spindle-tree) is seldom seen in our northern gardens, where it well deserves a home. In Renfrewshire it is quite hardy, and in the dull days of November it makes a brave show. True it has little to compete with, except the lingering glories of a few Michaelmas Daisies, Tritomas, or Autumn Crocuses, which it easily puts to shame.

The flowers are insignificant little yellow things, born in early summer, of no decorative value whatsoever, but the fruits are very striking, being of a brilliant red, and when they open and expose their seeds, which are orange in colour, the effect is not only striking but very pleasing. Branches may be used most effectively for house decoration.

With me it is a small tree or shrub some ten feet in height, but Loudon refers to it as a tree twenty-five to thirty-five feet high in Scotland. I find it is one of the few berried plants which birds seem to have no taste for; almost everything else of that nature seems to come in useful as a form of food for some species or another. E. europaeus will grow in any well-drained ordinary garden soil, and if, perchance, it claims a wall, it is entitled to it. There are quite a number of varieties but this is the only kind with which I am familiar. The wood is hard and was at one time used for making spindles, hence the name Spindle-tree. The plant has a further advantage, to Scotsmen at least; it is cheap, mine having cost 6s. per dozen. *Formakin.*

THE CEDAR GROVE ON MOUNT LEBANON.

THE information about the Cedars on Lebanon, taken from the French journal *Jardinage*, which appeared in the *Gardeners' Chronicle*, November 10, page 272, is not accurate, as the measurements given are grossly exaggerated. All who are interested in trees would like very much to know what has become of the Cedars which grew at the head of the Kadisha Valley in the Lebanon at about 6,200 feet elevation. This famous grove, which has been often described by travellers, was reported in the *Timber Trades Journal*, September 4, 1920, page 615, to have been almost totally destroyed by the Turks during the war, the timber being used as fuel for the locomotives of the Palestine Railway.

The trees are of great age, but owing to the extreme severity of the climate at the high elevation, and the very poor calcareous soil in which they stand, they are extremely slow in growth and make amazingly narrow rings annually. The growing season is remarkably short, the snow rarely quitting the basin, in which the grove is situated, before the end of July or the beginning of August. When Sir Joseph Hooker visited the grove in 1860, there were 398 trees, of which 15 where much larger than the others. The two largest had each a trunk 13 feet in diameter, or about 40 feet in circumference.

It is unnecessary now to go into any detailed description of this remarkable grove, which is in fact a sacred grove, dating from ancient times, as is evidenced by the strange ceremonies that are carried out under the shade of the Cedars on the eve of the Transfiguration of our Saviour. The Maronite Fathers and numerous pilgrims spend this night in dancing a kind of Pyrrhic dance, in singing and in feasting; and on the following day the patriarch celebrates high mass on an altar built under one of the largest and oldest Cedars. This festival is called The Feast of Cedars. The fact that the grove was sacred no doubt accounts in part for the preservation of the old trees through centuries.

The story of the grove is too long to tell here. I may hint at its significance by mentioning that the Valley of the Kadisha (*i.e.* holy) river, which takes its source amongst the Cedars, was one of the seats of the worship of Tammuz, the Syrian god, who was identified with the Phoenician Adon and the Greek Adonis.

The latest observations and measurements of the big trees in the grove were published by Monsieur Gadeau de Kerville, the author of a remarkable book concerning the old

FIG. 118. THE CEDARS ON MOUNT LEBANON, AS SKETCHED BY CAPT. S. P. OLIVER IN 1879.

Digitized by Google

trees of Normandy, who visited Lebanon in 1908. As a considerable number of travellers now go to Palestine it is very desirable that the grove of Cedars should be again accurately described and photographed, and the number of the trees and their dimensions ascertained. The judicious traveller will be well advised to study carefully Sir Joseph Hooker's admirable description and plan of the ground. The latter's notes and exact measurements of the different trees were given in the extinct periodical *Woods and Forests*, May 7, 1884, page 328. An article on the age of the Cedars of Mount Lebanon by the present writer was published in *Country Life*, December 11, 1915, pages 810-813, with a reproduction of Sir Joseph Hooker's plan of the grove, which shows exactly how the Cedars were grouped at the time of his visit in 1860. *A Henry.*—Fig. 118 shows what they were like in 1879.

VEGETABLE GARDEN.

PROTECTING BROCCOLI.

In many districts, it is necessary to protect Broccoli from severe frost.

The best method is to heel the plants over, which is done by taking a spadeful or more of earth out of the north side of each plant and pushing the stem of the plant into the hole formed. When this work is finished the head of each plant should face to the north, and the soil removed should be placed directly on the opposite side and trodden down solid with the foot.

If the work is done properly the head only will be visible, as the stem will be covered with soil. The object of this is to prevent the heads when frozen becoming thawed by the sun during severe weather, as this would seriously injure them the following night.

Should there be no severe weather, the time taken in performing this work is by no means wasted, as in mild weather with frequent rain, Broccoli is very liable to get sappy or woody. The slight check caused by breaking many of their roots acts in much the same way as root-pruning a fruit tree; it is beneficial, as it dries up much of the sap, and causes the plant to produce much better hearts than they would otherwise do.

In very severe weather the most forward plants may be lifted carefully and replanted closely together in pits or cold houses, covering the later varieties with a little dry litter, which should be removed forthwith when the weather turns milder.

WATERCRESS IN STREAMS.

The present is a suitable time to form Watercress beds in streams, for gathering stems next summer. The beds should not be more than four feet wide, with two alleys between them, and they should slope gently, as stagnant water or a very feeble flow generally proves very unsatisfactory to the Cress.

It is wise to have dams at intervals, as by this means the stream and Cress may be purified from time to time; it will also greatly reduce the number of insects that infest some streams, rendering the Cress almost unfit for use.

A suitable depth for the beds is eight inches, and the best Cress is grown in clay soil, although very good results are sometimes obtained from a sandy soil. Before planting the Cress the muddy refuse should be cleared out and two inches of good soil added. The shoots should be planted six inches apart each way, and covered with water to the depth of one inch. When the plants have reached the surface of the water, allow the latter to rise three inches above them, and, as the weather becomes colder, it is an advantage to let the plants be covered to a depth of six inches.

Cress planted in November should be ready for gathering throughout next summer; it is always advisable to use a knife for this purpose, and the shoots should be cut two inches long. Brown-leaved Cress is best to grow for any season. *W. Miller, Warley.*

PEA SENATOR.

I read with much interest the note on page 266 on this variety of Pea. My experience with Senator last year may be of interest to others. During the drought several of my rows of Peas, Senator included, failed before maturing properly, although some good Peas were gathered. Instead of pulling the haulm up, I had the sticks removed and the haulm cut down some six inches from the ground, not requiring the land for several weeks. I was greatly amazed to see that almost every plant of Senator broke into fresh growth. I carefully mulched each side of the rows and had the plants staked afresh and gave attention in watering, etc. I gathered a good crop of Peas which beat those of the variety Gladstone that was sown the second week in June, they were also free from Mildew. Some years ago I had an experience with the variety William Hurst. I sowed the seed in January, gathered a fine crop and left the plants alone after the Peas had finished and they broke into growth again and gave a second crop. I have always found that this Pea has a tendency to bear perpetually if left alone. I may state I tried this year to get a second crop from Senator in the same way as last, but the plants failed to break into fresh growth. *W. E. Wright, Henstaff Court Gardens, Pontyclun, S. Wales.*

BOKHARA CLOVER.

I READ with interest a little article in your issue of August 11, 1923, entitled "Bohkara Clover" and was especially interested to note that the writer considered it very doubtful whether cattle will take kindly to this Clover. This is the same doubt that has to a certain extent delayed the wide-spread use of this crop in the United States. In sections where the crop is not well known farmers still insist that cattle will not eat it, but it is nevertheless a fact that it is rapidly becoming one of the most important forage crops in the middle west. In Saskatchewan it is largely grown for both hay and pasture.

Sweet Clover is used at present more as a grazing crop than for hay, and as our farmers understand the nature of the crop better they are able to use it to greater advantage.

It is quite true that if cattle are turned on to Sweet Clover after it has attained some size, especially after it has commenced to bloom, and is consequently, becoming woody, they will not eat it unless starved to it. However, when turned on to Sweet Clover early in spring when the young growth is soft and luscious and there is little else that is green, the Sweet Clover is eaten greedily, If a sufficient number of stock is kept on the field so that the Clover does not make a growth of more than a few inches or a foot, it remains fit for grazing until about the middle of July.

An interesting practice which is gaining favour among the best farmers in the north-west is to have two fields: one of Sweet Clover in its first year and one in its second year. Cattle are turned on to the second year's growth in spring and kept there until early in July. With a good stand Sweet Clover will carry between two and three head of mature stock per acre from spring until July. Meanwhile the other field is making its first year's growth and by early July the plants have become large enough to graze. The cattle are now turned on to the first year's growth and the second year's growth is allowed to make seed.

This system once established will usually take care of itself so that the land need not be ploughed nor even disked as the Sweet Clover volunteers each year making a really permanent pasture. I believe these facts may interest your readers. *A. J. Pieters, In Charge of Clover Investigations, U.S.A. Dept. of Agriculture, Washington.*

RED PLANT OF STRAWBERRIES.

IN view of the seriousness of, and loss caused by, Red Plant disease in Strawberries, and the correspondence that has taken place on this subject, in the *Gard. Chron.*, I (as one who has been in close association with this serious trouble) venture to express an opinion and add a criticism of the treatment of Mr. Johns in this matter.

Mr. Johns should be given credit for having attributed this trouble to eel-worm so far back as 1920 (I can vouch for this fact), and although I differ with Mr. Johns and do not accept the recent paper by the experts on this matter as final, I think folk with scientific training should at least be given credit for observations made and work done. Many members of the Horticultural Educational Association will remember with what ridicule Mr. Johns' eel-worm theory was received at Long Ashton, at the meeting of the Association, only one short year before the Bristol experts made the "discovery" that Aphelenchus fragarieae is responsible for the trouble. Probably this was where Mr. Johns missed the mark; if he had not been so commonplace as to call it "eel-worm" he would have received credit for his work.

I have hinted that I am not entirely satisfied with the eel-worm theory. I have for the past four years had an opportunity of studying and watching this complaint. It must be remembered that other individuals have worked on this subject in the Tamar Valley, and although the results of many small experiments have been negative, the efforts of such persons as Messrs. Johns, Gough, Stoddart, and Walbank must not be overlooked. Although only a working instructor, with little time for research, I would like to give my views for what they are worth. Wherever Red Plant disease occurs there seems to be some correlation between this and a previous attack of aphis, eel-worm, or Strawberry-leaf spot. Marked or observed plants, particularly those attacked by aphis, have shown this, whilst others, unaccountably red—for example, when none of the three carriers are present—may be the result of damage by other pests or tools, and also by taking the runners from infected plants. It seems to me that some agent gains an entrance by the means mentioned and breaks down the normal functions of the plant. I also feel that we have much to learn concerning the "patch" and "cauliflower" troubles, and I think it is too early to record observations made on these. Our great need as growers is to find a way out of our numerous Strawberry troubles, by prevention, eradication, or immunisation. Whatever efforts are made in the above direction should be economic and practical. *Hy. W. Abbiss, Horticultural Superintendent to the Cornwall County Council.*

FRUIT REGISTER.

PEAR BERGAMOTTE ESPERIN.

THIS fine old Pear is a late variety of excellent quality, in season from February until April. The fruit is of medium size with a somewhat rough skin of a dark green colour, covered with brown russety dots and often tinted with faint orange colour. The eye is small and open, and the stalk about an inch long.

PEAR SANGUINOLE.

This is a remarkable variety of Pear owing to the juice and flesh being a blood red colour. I found a specimen of this variety at Dilwyn, a village a few miles from Leominster, the tree being of great age. The fruit is of medium size, with a green skin changing to pale yellow and dotted with grey dots, and a pale red colour on the side exposed to the sun. The flesh is red, crisp and juicy with a sweet flavour. This variety sells well in the northern markets. *Pomona*

PUBLIC PARKS AND GARDENS.

CHRYSANTHEMUMS IN THE GLASGOW PARKS.

THE parks department of the Corporation of Glasgow deserve congratulations on the magnificent display of Chrysanthemums on view in the City parks this season. In a large span-roof show-house in Queen's Park over 1,000 plants are arranged in undulating banks, consisting of bold groups of Mrs. G. Monro, His Majesty, A. F. Tofield, and Mrs. R. Luxford. These brightly-coloured sorts are flanked by groups of White Queen, Mrs. C. Beckett, Souv. de Wm. Clibran and Frances Jolliffe. Pink is a popular colour with the public, and the groups of Mrs. E. A. Tickle, Sir E. Letchworth, and Mary Poulton are much admired. Other noticeable sorts include Majestic, Mrs. G. C. Kelly, Miss A. E. Roope, Mrs. A. Davis, and Fred Green, a large purple flower, particularly effective in the mass.

In one of the houses scarlet and crimson are the predominant colours. Acalypha hispida (Sanderi), with long, drooping, crimson inflorescences, is arranged over a groundwork of Asplenium and Nephrolepis, with Clerodendron fallax, the red-berried Ardisia crenulata, and Rivina humilis, the last with long racemes of bright scarlet berries. Another house contains batches of the rose-coloured Ruellia macrantha, the blue-flowered Browallia speciosa major, Salvia splendens, and Humea elegans.

At Springburn Park the Chrysanthemums are arranged in a large three-sided group; from a broad base the plants slope gently to a good height, presenting three imposing walls of flowers. One side of a house is gay with perpetual-flowering Carnations and a display of these flowers is maintained by successive batches of plants for about nine months of the year. Ornamental Gourds of various shapes and colours are displayed in the Reid Winter Garden. These were grown under the rafters of the roof, and are a source of much interest to visitors. On the supports of the gallery, Tibouchina semidecandra, a large violet-coloured Melastomad, is flowering.

A feature of the Chrysanthemum display at the Botanic Gardens is the large number of dwarf, late struck plants in 6-inch pots with one bloom each, of exhibition size. These are arranged on the side stages in the two greenhouses opening off from the Kibble conservatory. Orchids flowering in the Botanic Gardens include Odontoglossum crispum in variety, Cattleya Bowringiana, C. labiata, Zygopetalum Mackayi, Epidendrum cochleatum, Vanda tricolor, V. suavis, and Maxillaria picta.

In the succulent house the red racemes of Greyia Sutherlandii are conspicuous. Interesting plants in bloom in the greenhouses are the yellow-flowered Candollea cuneiformis, Sparmannia africana, Whitfieldia lateritia, with terminal clusters of brick-red flowers; Acacia platyptera, Buddleia madagascariensis, having leaves and stems coated with white tomentum, and yellow flowers in branched racemes; Teucrium fruticans, and Abelia chinensis, the last a splendid plant for a pillar in the cool greenhouse. The foliage of small, pot-grown plants of Vitis Henryana has turned from green to ruby, with median silvery bands. In the exquisite stain of its autumnal colouring this hardy vine resembles the tropical Leea amabilis splendens at Tollcross Park, on the eastern fringe of the city, where there is also a display of Chrysanthemums and other seasonable flowering plants. *F. W. J.*

During the past three weeks an excellent display of Chrysanthemums has been on view to the public in Chalkwell Park, Westcliff-on-Sea. The greenhouse, a fine large building, was erected a year or so ago, and adds to the amenities of this pretty park. The house is now filled entirely with Chrysanthemums of all types, including large Japanese, Incurved, Single and Anemone-flowered sorts.

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

R.H.S. Award to the Grapes from Aldenham.—In your issue of November 17 (page 300) you report that the award given to the excellent exhibit of Grapes from Aldenham was a Gold Hogg Medal. On reference to the annual report of the R.H.S. I find it specifically stated that the Hogg Medal "is struck in silver-gilt, silver or bronze," and no mention is made of there being a *Gold* Hogg Medal! The official card placed on the Aldenham exhibit was one for a Silver-Gilt Hogg Memorial Medal! As I was one of the Committee which recommended the award to this exhibit, I should like in fairness to the exhibitor and the Committee to state that the Gold Medal of the Society was awarded, and *not* the Hogg Medal at all! And as this was by the unanimous vote of the Committee—not a dissenting voice, or motion against it—it seems very strange that a medal so unanimously awarded should be withheld, and another of lesser value substituted by the Council. I carefully examined the Grapes before the Committee met and, in my opinion, as well as that of other practical Grape growers, they were about the finest lot of Muscat Grapes staged anywhere this year, and had they been set up in open competition at Shrewsbury, Glasgow, or Edinburgh, they would have won a valuable prize. Having regard to the care and attention required—extending over a long period—to produce Grapes of such clean, even quality of berry, and size of bunch, I am still of opinion that the award of the Society's Gold Medal was a fair and just one. It seems to me an explanation is due from the Council to its Fruit Committee for over-riding their unanimous award on points of genuine merit. *N. F. Barnes, Eaton Gardens, Chester.*

[In view of the differences of opinion concerning the award made to the Grapes exhibited by the Hon. Vicary Gibbs at the meeting of the Royal Horticultural Society, on November 13, we wrote to the Secretary of the R.H.S., asking him to let us know what award the Fruit and Vegetable Committee recommended and what was the award sanctioned by the Council. In reply to our enquiry, Mr. Dykes wrote as follows: "The Fruit Committee, I believe, recommended a Gold Medal of some sort, possibly a Hogg Medal, to Mr. Vicary Gibbs' exhibit of Grapes, but the award made by the Council was a Silver-gilt Hogg Medal. Our attention here was drawn to the fact that you erroneously published a notice saying that a gold medal had been awarded to the Grapes and I think you must realise the undesirability of taking for publication the results of the Committee meetings. All that the Committee can do is to recommend awards which are made by the Council, and, as you see in this instance, it by no means follows, though, of course, it generally happens, that the recommendations will be accepted without alteration by the Council. In the circumstances, we should be glad if you would publish a note to the effect that the medal awarded was a Silver-gilt Hogg Medal and not a Gold Medal, as previously stated."—EDS.]

Apple Broad-Eye Pippin.—Owing to the scarcity of Apples in my immediate neighbourhood, I had to go some distance afield before obtaining a supply for personal use. In the direction of Thakeham (Sussex) I visited an orchard lying in a depression, where most of the trees were somewhat protected from the bitter northerly winds which play havoc with so many orchards during the flowering season. I was struck with the appearance of the trees, for they were old and decrepit, covered with Lichen, whilst many had split branches, thus showing utter neglect. I suggested the trees were from forty to fifty years old when, to my surprise, the owner stated they were a hundred years old. He further stated, his father—whom I saw—was seventy-seven years of age, and the orchard was thirty years old when he bought it. The trees had never been pruned, limewashed, or grease banded, and yet he had always obtained fair or average crops. I wanted cooking Apples of a late variety, and he produced an Apple called Broad-eye which he said would keep for a year. In appearance it is like a Bramley's Seedling, about the same size, but with a little less colour. The flesh is firm, in fact, quite hard. I cannot find this variety mentioned in *Hogg's Fruit Manual*. Is it known to any of your readers? *Worthing.*

[Broad-eyed Pippin is an Apple described by Hogg (see p. 31, fifth edition), as a very old English variety mentioned by Ray.—EDS.]

Colin-Pullinger Mouse Trap.—In February of last year I addressed a letter to you with regard to my experience of the usefulness of the Colin-Pullinger Balance Mouse Trap for the capture in a garden of field mice and voles, and have been much surprised to receive letters from different parts of the country, stating that the traps had not caught a single mouse. Knowing how well the traps work, it did not occur to me until recently to inquire of my gardener how my own had been catching, and I was astonished to learn that they had not caught any mice for a long time, although a drop of oil of aniseed had been placed on the flannel in the bait rack every few weeks. As oil of aniseed has been the only bait used for my traps for the past forty years, and only until now has failed to attract, it occurs to me that during the war some alteration was made in its manufacture, but it will be very difficult to prove this, for on inquiry I have learnt that most of this oil is distilled in China. I am also informed that there are several common brands on the market from which a portion of the active constituent (anethol) has been removed, so this may be the cause of the failure of the oil to attract. Several specimens have been sent to me, but, according to my sense of smell, they are not either so pleasant or so strong as the oil of years ago. I am informed that Messrs. Duke, Waring, Crisp and Co., 139, Wardour Street, London, W.1., who are now the sole manufacturers of the trap, on seeing my letter, attached a slip recommending oil of aniseed as a bait, and this probably has led to the oil being used more widely than it would otherwise have been done. However, knowing the fondness of mice for cheese, I had the scented flannel removed and substituted with a slice of cheese, about one-eigth of an inch in thickness, the size of the bait rack, and since this was done the traps have caught as well as they used to do. I feel it a duty to let you know what has occurred, for many of those who purchased traps, on seeing my letter, have probably been disappointed with the result, if they have followed the advice given to bait only with oil of aniseed. *Mark Hovell, Lemsford House, nr. Hatfield, Herts.*

Absence of Coloured Blooms at Chrysanthemum Shows.—I venture to make a few remarks concerning your observation *re* the absence of coloured blooms in two prize-winning exhibits at the recent exhibition of the National Chrysanthemum Society. This lack of colour I attribute to faults in the drafting of the schedule, and to the judges' award in favour of size in preference to colour. Exhibitors are, therefore, encouraged to include the larger blooms which, unfortunately, present only the dull colours and are, in my experience, more easy to grow to perfection than the more highly-coloured sorts. Those exhibitors who attempt to have their collections as attractive as possible generally go unrewarded because they have failed to make the florets and their blooms hang over the sides of the stands. Nothing gave me more pleasure than the three fine exhibits in the Wells Memorial Class at the National Show; each was represented by flowers of all the best colours. *G. J. Miller, Codicote Lodge, Welwyn.*

SOCIETIES.

ROYAL HORTICULTURAL.

Nov. 26.—Doubtless the severe frost and the foggy weather of the preceding day and during the early morning of Nov. 26 were responsible for the small exhibition at Vincent Square, and also for the small attendance. Three large specimen Chrysanthemum plants proved attractive, and suggested comparisons between the present and old-time methods of plant cultivation for exhibition. A few Alpine plants, some Succulents, Carnations, Orchids, Chrysanthemums, Begonia Gloire de Lorraine, shrubs, dried flowers, and clipped trees were the principal subjects shown.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Messrs. J. O'Brien (Hon. Secretary), Gurney Wilson (Assistant Secretary), R. Brooman White, J. Wilson Potter, T. Armstrong, H. T. Pitt, Fred. K. Sander, H. G. Alexander, Chas. H. Curtis, J. Cypher and the Hon. Henry McLaren.

FIRST CLASS CERTIFICATES.

Cypripedium Gwen Hannen (*Florence Spencer* × *Christopher var. Grand Duke Nicholas*), from G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. W. H. Page). A grand hybrid of the type of C. Christopher, which has been one of the leading features in this section of hybrids raised at Chardwar. The fine white dorsal sepal is over four inches in width, a broad band of purple running up the middle and smaller purple lines on each side The large petals and lip are honey-yellow, tinged with chocolate purple.

Cypripedium Chrysostom var. Amy Moore (*Christopher var. Grand Duke Nicholas* × *Pyramus magnificum*), from G. F. MOORE, Esq. The white sepal is of fine substance, being 4¼ inches across, the basal half emerald-green spotted with purple; both the petals and the lip are broad and well displayed, the colour being greenish-yellow tinged with purple.

Cypripedium Chrysostom var. Richard Fort, from G. F. MOORE, Esq. The dorsal sepal is white with purple spotted lines from the base, the petals and lip of honey-yellow, tinged with chocolate-purple.

Cypripedium Prince Albert var. Mecca (*Tommy Curte* × *Pyramus magnificum*), from G. F. MOORE, Esq. The dorsal sepal is white, evenly spotted with claret-purple; the very broad petals are tinged with mahogany-red on the upper half and spotted on the lower part. The lip is yellowish, tinged with purple.

CULTURAL COMMENDATION.

To Messrs. ARMSTRONG & BROWN, Orchidhurst, Tunbridge Wells, for a beautiful specimen of Lælio-Cattleya Schroderæ var. The King (L.-C. Bella alba × C. Maggie Raphael alba), with a fine inflorescence of seven large white with a crimson-purple lip and a small yellow disc.

A Silver Floral Medal was awarded to Messrs. SANDERS, St. Albans, for an excellent group with a centre of Dendrobium Phalaenopsis Schroderianum and white Vanda Watsonii. A fine and varied selection of Cypripediums formed the body of the group with a selection of Cattleya Hardyana alba and other hybrid Cattleyas, the two novelties being C. Cressidæ (Cooksonii alba × Hardyana alba), a very pretty and distinct white flower with a transverse, bi-lobed, crimson-purple band on the lip; and Lælio-Cattleya Troila (C. Rex × L.-C. Canhamiana Rex) with pretty Primrose flowers, and crimson-purple lip. A very interesting selection of species was also shown, including Dendrobium cymbidioides, Maxillaria venusta and other Maxillarias.

Floral Committee.

Present: Messrs. H. B. May (in the Chair), E. A. Bowles, G. Reuthe, J. F. McLeod, Donald Allan, H. V. Warrender, Reginald Cory, H. D. McLaren, Thos. Stevenson, W. H. Page, H. J. Jones, J. Jennings, C. R. Fielder, Clarence Elliott, W. Cuthbertson, J. B. Riding, Chas. E. Pearson, W. B. Gingell, A. Turner, D. B. Crane, W. P. Thomson, and W. J Bean.

There were sixteen entries before the Floral Committee, but no award was recommended. Among Chrysanthemums submitted, the varieties Mr. A. Robertson, a pink single, and Mrs. Wilfred Ashley, a pink terra-cotta decorative sort, were very promising.

GROUPS.

Chrysanthemums again were prominently displayed and in large quantities. On either side of the entrance Messrs. W. WELLS & Co. and Messrs. KEITH, LUXFORD & Co., had extensive collections of excellent blooms. Amongst the large-flowered Japanese blooms shown by Messrs. W. WELLS & Co. were excellent specimens of Peace, Louisa Pockett, and Wm. Turner. Amongst their single-flowered sorts Molly Godfrey, Margaret and Bronze Molly were very prominent, while the many well-coloured blooms of decorative type included December Gold, Nagoya, and Baldock's Crimson (Silver Flora Medal).

Messrs. KEITH LUXFORD & Co. gave the central position to an unusually good collection of tiny Pompons. Their exhibition Japanese varieties included magnificent specimens of Helena Margerison, H. V. West, Sulphur Queen, and Mrs C. Edwards. Large singles were also of great merit, and amongst these were vases of Nora, Cannell's White, Reginald Godfrey, and Absolute (Silver Flora Medal).

Several decorative varieties of Chrysanthemums grown as sprays were set up by Mr. F. G. WOOD, who staged such sorts as Golden Marvel, Cranfordia, and Ashstead Pink. He also showed his miniature alpine gardens.

A large group of magnificent plants of Begonia Gloire de Lorraine were exhibited by J. B. BODY Esq. (gr. Mr. C. Hay), Hindhead Court, Hindhead. These very large plants bore countless numbers of flowers and illustrated especially skilful cultivation (Silver Gilt Banksian Medal). A smaller collection of the same Begonia was shown by Mrs. CONSTANCE JOY (gr. Mr. A. J. Bright), Marylands, Bentley, but most unfortunately the plants had been damaged by frost in transit. On a floor space Mrs. JOY showed three particularly good specimen plants of Chrysanthemum Mrs. R. Luxford. Each bore about 150 beautiful flowers (Silver Banksian Medal).

Mr. SYDNEY SMITH arranged a collection of Succulents with considerable taste. There were small plants of Cereus, Maxillaria, Echinocactus, Opuntia, Sempervum and Sedum and all were exceedingly well grown (Silver Banksian Medal).

Carnations were especially bright and good. In addition to a small collection of Dianthus Allwoodii, Messrs. ALLWOOD BROS. set up excellent vases of such perpetual-flowering Carnations as Edward Allwood, Wivelsfield Claret, Jazz, Chintz and Topaz (Bronze Flora Medal).

Amongst the many valuable sorts displayed by Mr. C. ENGELMANN were Enchantress Supreme, Tarzan, Topsy, Peerless, Laddie, and Delice (Silver Flora Medal). Messrs. STUART LOW AND CO. again staged a large quantity of the beautiful pink Eileen Low, with Coquette, Amos Grove, Lady Inverforth, and White Pearl (Silver Banksian Medal).

An unusual but interesting and useful exhibit was that of "Everlastings," set up in an admirable manner by the FRENCH INTENSIVE GARDENS LTD. The sprays had been well handled since they were cut so that the colours were very good. This exhibit included Helichrysums, Acroclinium, Statice, Gypsophila, Tamarix, Physalis and Agrostis. The method of writing the names of the different species on Laurel leaves added to the effect of the collection (Bronze Banksian Medal).

A varied and interesting collection of ornamental shrubs was arranged with considerable taste by Messrs. L. R. RUSSELL, LTD. Such shrubs as Eleagnus pungens picta aurea and Euonymus ovata alba were splendidly coloured. Other attractive shrubs included Cotoneaster pannosa and Skimmia japonica heavily berried, and a standard Rosemary in full bloom. On an adjoining table Messrs. RUSSELL showed especially well flowered examples of Jacobinia chrysostephana and Tillandsia Lindenii (Bronze Flora Medal).

New Zealand Veronicas such as V. cupressoides and V. selaginoides, suitable for planting in the rock garden were shown by Messrs. BAKERS, LTD., who also had vases of decorative Chrysanthemums in an undisbudded state.

A large collection of Conifers was assembled by Mr G. REUTHE. These were shown as small shapely bushes and as cut branches. In some instances the branches bore their cones, and there was also a collection of cones of Pinus, Abies, Cedrus and Picea on view. The specimens of Abies Webbiana, A. bracteata, Podocarpus chilana and Pinus Teocote attracted considerable attention (Silver Banksian Medal.

The COUNTESS CAWDOR (gr. H. Windibank), Frensham Hall, Hazlemere, sent an admirable collection of Pernettya macronata which bore an unusual quantity of berries. Several forms were included, and one, which bore bright crimson berries, was of especial value (Silver Banksian Medal).

Mr. ELISHA J. HICKS again showed splendid blooms of the rich Pink Rose America, and Mr. J. KLINKERT brought well-trained topiary specimens.

Miss WINIFRED WALKER, Mrs. ADIE, Miss ALLEN WARRINGTON, Miss G. DORRIEN-SMITH, Miss A. F. WILKINSON, Miss MAUDE ANGELL and Mrs. TOWNSEND, took advantage of the dull season to exhibit paintings of garden scenes and floral studies for which various medals were awarded.

Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (Chairman), J. Cheal, H. S. Rivers, Geo. F. Tinley, W. F. Giles, G. Reynolds, G. Kelf, Ed. Beckett, Ed. Harriss, T. Pateman, A. Bullock, J. Harrison, W. H. Divers, E. A. Bunyard and A. N. Rawes.

There were only two exhibits submitted to this Committee, the one, some excellent pods of Climbing French Bean Tender and True which Mr. Geo. Reynolds brought from Mr. Leopold de Rothschild's garden at Gunnersbury Park, Acton, for which a Cultural Commendation was recommended, and the other, Apple George Carpenter shown by F. C. Stoop, Esq., West Hall Gardens, Byfleet (gr. Mr. G. Carpenter), which was recommended at a previous meeting for inclusion in the trial of commercial varieties at Wisley. This Apple is the result of a cross between Blenheim Pippin and King of the Pippins, and it has the high colouring of the latter parent and the eye and texture of the Blenheim parent. It is a very showy Apple, but the specimens had apparently been kept in a rather dry place, for they were a little shrivelled. It is an Apple of merit, but the Committee did not think it was sufficiently superior to existing varieties to be worthy of an award.

In the hall Messrs. GEO. BUNYARD, LTD., displayed a very interesting exhibit of Apples for the special purpose of showing varieties in season, and we understand that they propose to show collections at following meetings whilst Apples are available. The fruits shown on this occasion were splendid specimens of Pineapple Russet, Royal Jubilee, Rival, Blenheim Pippin, Baumann's Winter Reinette, Lord Derby, Allington Pippin, Peasgood's Nonsuch, Cox's Orange Pippin, Warner's King, Cockles Pippin and Bismarck.

HULL & EAST RIDING CHRYSANTHEMUM.

THE Hull Chrysanthemum Society resumed its annual exhibition on November 21 and 22, after the shows had been in abeyance for a period of ten years. The 23rd Exhibition was originally fixed for a date in November, 1914, but with the outbreak of war in that year the exhibition was cancelled.

The City Hall, Hull, is splendidly adapted for exhibitions such as the one under notice and on the present occasion the Society also had the use of the Art Gallery, where cut flowers and fruits were seen to great advantage. In the City Hall groups of Chrysanthemums were tastefully disposed in the centre and

Digitized by Google

mirror groups were arranged at the base of each pillar and at the two ends of the Hall. Where there were not enough exhibits to fill each of the spaces allocated to groups, Mr. H. B. Witty, the Parks Superintendent, and his staff arranged charming groups of Chrysanthemums of a representative character, and in ideal form and condition. The show of the present season worthily maintained the high reputation which the Hull Show has enjoyed in the past. In some instances the classes were not well filled, but, generally, there were sufficient exhibits to make a keen competition.

The Right Hon. T. R. Ferens, P.C., J.P., continues in the position of President, which office he very ably fills, and he is supported by a very enthusiastic Committee, while Mr. H. Harland and Mr. J. White, are joint Honorary Secretaries. The Exhibition was opened by the Lord Mayor of Hull before a distinguished company, and music was discoursed by the band of the Coldstream Guards. The Society is to be complimented on the very able manner in which every detail of the Show was carried out. It was possible to purchase a schedule of the classes giving the list of entries in each class and the awards made within about half an hour of the conclusion of the judging.

GROUPS.

There was only one exhibitor in the class for a group of Chrysanthemums interspersed with foliage—arranged on the floor in an oblong twelve feet by eight feet. This was shown by Mrs. ARTHUR WILSON, Tranby Croft (gr. Mr. W. J. Earl). It was an attractive exhibit but two huge vases in the centre of the group might have been improved.

There were four exhibits in the class for a mirror group of Chysanthemums, miscellaneous flowers and foliage, arranged on a ground space not exceeding twelve square feet. A charming exhibit of the single-flowered Chrysanthemum Florrie King (pink and white) arranged on both sides of the mirror, and Begonia Gloire de Lorraine, with Pandanus and other foliage plants at the base, made a display well meriting the award of first prize which it received. This exhibit was put up by Mr. A. C. STOREY (gr. to the President, Holderness House, Hull). Mr. EARL gained second prize with an attractive group, and R. H. MICKS, Esq., Hotham House, Brough (gr. Mr. B. Gray), came third with a bright display.

CUT BLOOMS (OPEN CLASSES).

The leading class for cut flowers was that for twenty-four Japanese blooms in not fewer than eighteen varieties, shown on boards, for which a silver cup and attractive money prizes were offered. There were three competitors and each of them staged blooms of splendid quality. First prize was awarded to T. M. G. HEWITT Esq. (gr. Mr. F. J. F. Fleming), Weelsby Old Hall, Grimsby; his best flowers were of Lady Talbot (2), Majestic (2), Louisa Pocket (2), W. Rigby (2), Mrs. Gilbert Drabble (2), Mrs. R. C. Pulling, Princess Mary, Gen. Petain, Mrs. G. Hardy, Mrs. A. Davis, Queen Mary (2), Mrs. Chas. Fox, Mrs. J. Gibson, Mrs. J. Balmer, and Lady Stuart of Wortley. Second prize was awarded to Mr. H. WOOLMAN, Shirley, Birmingham, some of whose blooms, notably those of Majestic, W. Rigby, Queen Mary and Norman Chittenden, were very fine. Third prize was awarded to JAMES ARMITAGE, Esq., Clova, Harlow Oval, Harrogate (gr. Mr. Robert Jones).

There were only two exhibits in the class for six vases of three incurved blooms, in six varieties, one variety in each vase. First prize was awarded to Mr. ARMITAGE who shewed popular sorts quite well. No other prizes were awarded in this class. The five competitors in the class for one vase of three blooms of a yellow Japanese variety made a capital display, first prize being won by T. FERENS, Esq. with splendid blooms of Mr. Rigby. T. HEWITT, Esq., was second with good specimen blooms of Mrs. R. C. Pulling, and ARNOLD LECKITT, Esq., Westerland, Elloughton, Brough (gr. Mr. W. P. Barnes), was third, also with Mrs. R. C. Pulling.

There were five exhibitors also in the class for one vase of three blooms of a white Japanese variety, and MISS BENNETT, Westlands, Grimsby (gr. Mr. G. B. Burrows), was placed first with grand examples of Queen Mary; second, Mr. WOOLMAN, with shapely blooms of Mrs. Gilbert Drabble; third, J. ARMITAGE, Esq., with Wm. Turner.

Only three exhibitors came forward in a similar class for a pink Japanese variety; Mr. FLEMING was first with good examples of Mrs. F. J. F. Fleming, Mr. EARL was second, and Mr. JONES third. The five exhibits in the class for one vase of three blooms of bronze or other dark Japanese in one variety made an interesting display. First prize was awarded to Mr. H. WOOLMAN, for large, fairly even blooms of Majestic. Mr. FLEMING was second with large, though less pleasing, blooms of the same variety, and third prize went to Mr. STOREY, for beautifully finished blooms of Mrs. G. Monro. A useful class was that for one vase of six Japanese blooms in six varieties. Good blooms of high colour won first prize for Mr. H. WOOLMAN; second, T. HEWITT, Esq.; third, J. ARMITAGE, Esq.

It was unfortunate that only two competitors entered in the class for two vases of three Japanese blooms; magnificent examples of Majestic and Queen Mary won first prize for Mr. WOOLMAN, and splendid examples of Lady Talbot and Majestic secured second prize for T. HEWITT, Esq. We noted with interest the class for six vases of reflexed decorative Chrysanthemums (really, disbudded market varieties). The three exhibits contained useful material, and first prize was won by Mr. MONTAGUE STATHER, Arlington Nursery, Cottingham, who showed Mrs. Buckbee, Miss J. Stather, Miss Olive Dumsday, Wellington Wack (very pretty), Sorcerer and Sunshine; Mr. WOOLMAN came second with excellent flowers, and W. H. THICKETT, Esq. (gr. Mr. J. Irvine), Bradley Gardens, near Grimsby, was third.

One of the most interesting and attractive classes in the whole show was that for a table of single varieties arranged for effect, one colour in each vase or stand, with natural undyed foliage, exhibits to face one way and to be arranged on a table space 10 feet by 2 feet, 6 inches. There were only two exhibits but they were excellent; a highly artistic display won first prize for Mr. M. STATHER, to which prize a Silver Cup was also attached. There was only one defect in this display, the exhibitor did not make so much of the central background as he might have done. His exhibit, otherwise, left nothing to be desired. His best varieties were: Mildred (bronze), Susan (yellow), Absolute (bronze), Sandown Radiance (chestnut), Mrs. W. Smith (cream), Edith Dimond (bronze), Robert Collins (apricot), and Floria (pink). Mr. WOOLMAN followed very closely, but his exhibit lacked the artistic finish of the first prize display, although his blooms were splendid.

DECORATIVE OPEN CLASSES.

Mr. STATHER led among four exhibitors in the class for a basket of single Chrysanthemums arranged for effect, and Miss M. NOBLE, 3, Northgate, Cottingham, came second. The same exhibitor also won first prize for a table of Epergnes, bouquets, button-holes and other floral arrangements, illustrating the decorative value of the Chrysanthemum.

LADIES' DECORATIVE CLASSES.

The five dessert table decorations arranged by local ladies were a centre of interest for many visitors. The class provided for a table completely laid out for dessert for six persons, Chrysanthemum flowers only admissible, with any kind of natural foliage: and fruits allowed. The first prize was won by Mrs. HAROLD SISSONS, North Ferriby. This exhibitor used a rather small, crimson, single Chrysanthemum very effectively, and in other respects the arrangement was very good. Most of the other competitors used rather dull, uninteresting, bronze Chrysanthemums, and there was little to choose between them. Mrs. E. TINLEY SISSONS, Cottingham was placed second, and Mrs. EDWIN ROBSON, Sutton, third.

Competition was good for a bowl of Chrysanthemums for a dinner table decoration. First prize deservedly went to Mrs. E. ROBSON for a reddish-crimson, single variety, and second and third prizes went to Mrs. M. E. THOMPSON and Miss E. F. HARLAND respectively.

LOCAL CLASSES.

These were well represented and many fine exhibits were staged. One class calls for special mention, viz., that for six vases of single Chrysanthemums, five stems in each, disbudded to one flower on each stem, in not fewer than four varieties, one variety in each vase. There were six competitors, and Mr. ROBERT THOMPSON, 37, Woodlands, Beverley, won premier honours with a beautiful series of flowers, showing such sorts as Molly Godfrey, Susan, Elsie Waters, Edith Dimond, Catriona and Phyllis Cooper; Mr. A. E. WILSON, Hull, was placed second, and Capt. J. H. BROADLEY, Welton House, Brough, third.

VEGETABLES AND FRUITS.

The competitions in the vegetable classes appeared to be chiefly confined to allotment holders of which there are many groups and associations. Competition in most of the fruit classes was poor, but some of the exhibits were highly meritorious.

Obituary.

Julius Roehrs.—We regret to learn of the death of Mr. Julius Roehrs, President of the Julius Roehrs Co., of Rutherford, New Jersey, U.S.A. Mr. Roehrs was a great lover of Orchids, stove plants and greenhouse plants, and was the moving spirit in the firm's business as nurserymen, seedsmen, and landscape contractors. Death took place on October 31 following a brief and severe attack of cerebral meningitis.

TRADE NOTES.

THE Council of the Chamber of Horticulture on the 14th ult. discussed the Government's Draft Rating and Valuation Bill, and it was unanimously agreed that the principle of the Bill as a whole be adopted. It was the general opinion of the meeting that the time had arrived for reform in rating and valuation and that as regards its application to horticulture this Bill might afford the opportunity of obtaining a better basis of valuation. A proposition was put forward to make an application for glasshouses to enjoy the same relief as agricultural land, but it was considered highly improbable that an attempt to introduce such an amendment in the Bill would be successful, but that endeavours should be made to obtain concessions as regards depreciation.

It was stated that the railway companies have recently issued a number of terms and conditions agreed to between the Traders' Co-ordinating Committee and the Railway Companies for merchandise carried by merchandise train at owners' risk. These terms and conditions are more favourable to traders than those at present in force and are the outcome of objections lodged by various associations, including the Chamber of Horticulture. Following negotiations with the Railway Clearing House, the Companies submitted at the end of July last, new rates for the cut flower traffic from the Spalding and Wisbech areas which at first appeared to be favourable, but it has since been definitely stated by the Railway Clearing House that the rates submitted are subject to a 50% increase. This does not improve the position to any appreciable extent and no doubt the Council will consider further action necessary.

ANSWERS TO CORRESPONDENTS.

CHECKING WOODY GROWTH IN FRUIT TREES: *R. J. A.* We have not heard of any process of boring the stem and injecting some preparation to check the growth of fruit trees. Possibly you are thinking of ringing the bark, which has sometimes been done to check growth and promote fruitfulness. But any system which involves wounding the stem is undesirable, owing to the risk of introducing disease. The only safe and reliable methods of steadying growth and inducing fruitfulness are (1) root-pruning, and (2) moderating the usual pruning of the head. The former is the usual method adopted in gardens. The latter is more often followed by market-growers, for whom root-pruning on a large scale would be too expensive. If pruning can be confined to mere thinning out for a year or two, or even if the leaders are allowed to grow whilst the laterals are not pruned too closely, the trees will almost invariably come into fruit, provided that they are not forced with manure.

NAMES OF FRUIT: *J. T. W.* Small Apple, Norfolk Stone Pippin; large, Blenheim Pippin.—*C. E. B.* 1, Flander's Pippin; 2, Lady Henniker; 3, Bramley's Seedling; 4, Reinette du Canada; 5, Pear Beurré Diel; 6, Broad-eyed Pippin.—*Constant Reader.* Dark Apple, Norfolk Beefing; red, Lord Burghley.—*A. S. W.* The variety is Blenheim Pippin. The stock possibly makes the difference. There are a few trees in Kent called Bastard Blenheim, the fruits of which are considered of better flavour. The stock, whether Crab or Paradise, has some influence on the shape of the fruit, and possibly the flavour; the nature of the soil also is a factor in this respect.

WATER IN A TARRED TUB: *D. M. M.* If the tub is tarred inside and the tar allowed to become perfectly dry, water stored in it should not have any harmful effect when it is used in a greenhouse. It will be advisable, however, to first fill the tub with water and allow this to stand for a few days and pour it away before filling it with the water which will be used in the house.

NAMES OF PLANTS: *G. H. J.* 1, Abutilon Sawitzii; 2, Ophiopogon Jaburan; 3, Helxine Soleirolii; 4, not recognised.—*W. R. R.* Phytolacca decandra.—*M. N.* 1, Veronica angustifolia; 2, V. Diamant; 3, Viburnum Opulus (Guelder Rose); 4, Centaurea rutifolia.

GRAPE PRINCE OF WALES: *T. M.* The perfect fertilisation of the flowers of the Prince of Wales Grape is rarely effected without artificial aid. It is therefore advisable to collect pollen from other varieties, especially Black Hamburgh and Alicante, and fertilise the flowers of Prince of Wales with this. It is a good plan to leave three or four buds when pruning this variety, or better still to grow it on the extension system and shade the vinery lightly when the sun is very strong.

VINE AND PEACHES INFESTED WITH RED SPIDER.: *K.* When pot plants are kept in vineries or Peach houses throughout the winter months, it is difficult to keep the vines and Peach trees free from red spider. It is a good plan to anticipate an attack by dressing the vine rods and Peach trees with a solution of Gishurst Compound, made according to directions given by the makers. It is also necessary to keep careful watch for an attack in the spring. A dry atmosphere, and especially one produced by means of artificial heating, is conducive to attacks of red spider, while dryness at the roots of the vines and trees and improper ventilation are other contributing causes. The roots should be watered freely during the growing season and the atmosphere kept moist, especially during periods when the temperature is high. In the case of an attack of red spider while the vines or trees are in full leaf, the foliage should be washed with soapy water and sulphur and syringed frequently with clear, soft water.

CUT FLOWERS.

REMARKS.—Supplies were sufficient to meet all requirements during the past week, with the exception of Roses and Violets. Prices continued steady throughout the week, and this was the case with the imported flowers, of which only Parma Violets varied in price owing to the erratic and uncertain arrivals of these flowers. There appeared to be a falling off in supplies from home growers this morning, more especially amongst Roses and Carnations. Owing to the colder weather Roses promised advance in price if the wintry weather continues. Of Chrysanthemums there appear to be sufficient disbudded blooms both white and coloured, for present requirements, amongst "Spray" Chrysanthemums, Wilcox (bronze), and Winter Cheer (pink), are the latest arrivals. A few bunches of Roman Hyacinths were on sale to-day, being the first consignment this season. White Lilac from Holland is arriving in much better condition. Anemones, Acacia (Mimosa), Narcissus, Scarlet and Cerise Ranunculus, Safrano Roses, Parma and Single Violets, constitute the main supply of the French consignments. Single Violets from that country are not reliable. Paper White Narcissus is also arriving in excellent condition, and is moderate in price. Richardias (Arum) and Smilax, are the chief supplies from the Channel Islands. A few Violets have been received from this quarter, but they suffer in transit, and are practically unsaleable. Further supplies are expected from French growers shortly.

ABSTRACT PUBLISHED IN NOVEMBER.

Transplanting Seedlings.—Patent No. 203,275.—An appliance particularly for transplanting seedling trees has been invented by Mr. A. M. Morrison and Mr. R. I. Morrison of Alness, Burnside, Rutherglen, Lanarkshire. The device is constructed with metal supporting members, suitably stiffened and combined with a spacing member. The transplanter may have timber members, in which case the spacing member is a fitting forming part of or secured to a table on which the transplanter is filled with the young plants. The spacing members are clamped to a bar secured to the table edge, each member having a notch to receive a plant. When the plants are positioned, the other board member is swung over and clamped on to the stems by suitable means, such as by ings. The spacing device may be a bar notched or grooved, or the table edge may be similarly shaped to position the plants. The resilient member of the transplanter may also be notched or grooved to receive the stems of the plants.

This list is specially compiled for *The Gardeners' Chronicle*, by Messrs. Rayner and Co., Registered Patent Agents, of 5, Chancery Lane, London, from whom all information relating to Patents, Trade Marks and Designs can be obtained gratuitously.

The November Frost.

No gardener who happened to be in a district where the sun shone during the days of the severe November frost will ever forget the scene of magical beauty which the garden presented on the morning of November 25. The crystalline frost which embellished all vegetation made the upstanding shoots of Broom look like sheaves of spears. Wherever the frost touched green things it covered them with a white mantle, but wherever it tried to put its cold finger on red-leaved or red-stemmed plants it failed, and the red centres of Androsaces on the walls and the red stems of Dogwood and Willow (Salix cardinalis britzensis) refused to have their brightness hidden by the frost. This physiological puzzle still awaits an explanation. From the point of view of garden management the frost was no unmixed evil. It may have destroyed some tender things particularly if they had been recently planted or transplanted. But wise gardeners in the latter case had surely discounted this risk by scattering leaves over the soil round the roots, and in the case of more precious things, covering them with Bracken. The chief loss due to the frost fell on Potato growers who had not been fortunate enough to get the whole of their crop lifted. That which remained in the soil is, we fear, irrevocably lost. Other loss there may and and probably must be of nursery and florists' stock which found itself in transit and exposed at railway junctions to hard weather. It is likely on the other hand that the gardener who was well forward with the digging of heavy land will reap a good reward for his timeliness. After the "bone" has gone out of the ground it should work in kindly fashion, and also, as it is to be hoped, not a few soil pests and weed seeds may have received their quietus. Vegetation this year has, doubtless owing to the generally wet autumn, shown such a reluctance to leave off growing that the frost may prove to have done more harm than seems apparent now. It will be interesting to see whether this applies to those plants which have in certain districts a reputation for tenderness. Of these Cupressus macrocarpa is one. So far as may be judged, where this Conifer fails it is due rather to its habit of excessive and prolonged growth than to a real tenderness. A young hedge under our observation, the members of which had made extremely rapid growth this year, should provide a test of this theory. These Cupressus had certainly not ripened their wood when the frost fell upon them, and it remains to be seen whether they will be found to have been permanently damaged. It is curious to notice in gardens in times of severe frost how the domesticated animals stand stock still. Instead of running about as we might expect they remain stationary. Is this because the cold air which they would meet when in active motion would dislodge the warm air entangled in their feathers which remains to form a blanket whilst they are still? The early frost this season doubtless caught certain gardeners napping, and it was a forcible, and, in view of the mild winters of recent years, perhaps a necessary reminder that tender plants should be housed and preparations made for protecting the less hardy subjects in the garden even before October is over. The frost was welcomed most by growers of indoor flowers for market, for Covent Garden and other markets were filled with autumn flowers from out-of-doors, and these reduced the value of choice material in many cases below that of production. The frost also completed the defoliation of deciduous trees and shrubs, and what promised to be a late season for lifting was made earlier, to the advantage of the tree and shrub nurserymen, who find a difficulty in executing their orders when the few weeks at their disposal are curtailed by late growth.

Our Coloured Plate.—The supplementary coloured plate to the present issue illustrates an inflorescence of the beautiful stove plant Ixora macrothyrsa, sometimes known as I. Duffii. It is a native of the South Sea Islands, and was introduced in 1878. The large trusses of deep red flower are exceedingly handsome, and they are set off by the large, deep green leaves which often attain a length of ten inches or more; indeed, the species is one of the finest of the genus. The Ixoras are splendid subjects for the stove and warm greenhouse, as they are of simple culture and may be propagated very easily. They grow well in a compost consisting of a mixture of fibrous loam, peat, and sand, with a little broken charcoal added. Large specimens may be grown without repotting for several years, provided they are fed occasionally with some form of liquid manure.

Diamond Jubilee of a Gloucestershire Society.—There are very few societies devoted to the interests of agriculture and horticulture that have celebrated their diamond jubilee, but the Gloucestershire Root, Fruit and Grain Society accomplished this feat on the 9th ult. when the Sixtieth Annual Exhibition of Flowers and Produce was held at the Shire Hall. These shows were held through the darkest days of the war, and have a time-honoured association with the civic authority of the old City of Gloucester. On November 9th the Mayor is appointed, and the first business of the newly-appointed Mayor, with the Corporation, in their robes of office, is to proceed to the Shire Hall and open the exhibition. The ceremony seems to have grown old with the Society, but it never loses its novelty, never fails to attract an attendance, and the way that the West Country crowd sings "God Save the King," after the opening function is over, is worth going some distance to hear. The Gloucester Root, Fruit and Grain Society had a small beginning. It orginated in fact over a bet made by two farmers as to which had the heaviest roots, and Mr. William Priday is, and has been, the only Chairman. In his long term of office he has probably welcomed more mayors to an opening function than any living man. In its sixtieth year the Society has a great influence on the agricultural and horticultural interests of the county, for in addition to the annual show it gives prizes for the best cultivated farms, field crops, root crops, and the best managed orchards, and counted amongst its members are many of the leading agriculturists in Gloucestershire. The annual show is a kind of reunion of the latter; they were at the Shire Hall on the 9th ult., and if owing to the shortage of fruit crops this year the show was smaller than usual, the interest seemed quite as keen, and county farmers mixed with the city people just in the old sweet way. A few years before the War an addition was made to the show in the shape of an exhibition of produce organised by the County Education Authority, and open to elementary schools and adults who have received instruction under the above authority. This exhibition has grown so much in size and improved so much in quality that it now makes a second show, and the display on the 9th ult. was considered to be the best yet held. It consisted of fruit, vegetables, cheese, butter, eggs and poultry, and not the least interesting section was the collection of vegetables grown in elementary school gardens, with accompanying note books. It may be observed in passing that a few years ago visitors to the show used to smile at the produce in the school garden classes and remark that it was quite good for boys; but now some of the finest specimens in the whole exhibition come from school gardens, and the boys unaccompanied by teachers bring the produce to the show and arrange it. In another part of the building there was one of the finest exhibitions of honey ever seen in the county, arranged under the auspices of the Gloucestershire Beekeepers' Association. The secretarial duties for this interesting exhibition at which farmers, fruit growers, gardeners, poultry-keepers, bee-keepers, and school teachers join hands, so to speak, are carried on by Mr. Sidney Starr for the Root, Fruit and Grain Society, and Mr. G. H. Hollingworth, Agricultural Organiser, for the County Education Authority.

Legacies to Gardeners.—The late Mr. Harry Manstield, J.P., of Moulton Grange, Northamptonshire, left a legacy of £250 to his gardener, Mr. Harry French. Mr. Manstield also left legacies to others of his servants, including £250 to his farm foreman and a sum equal to six months wages to each of his other gardeners and outdoor servants. The late Sir Albert John Hobson, of Esholt, Ranmoor, Sheffield, left an annuity of £50 to his gardener, Mr. John Cowan, if still in his service and not under notice. The late Mrs. Frances Ralle, of Rossefield, Bradford, bequeathed £50 to her gardener, Mr. Robert Mellish.

The Orchid Club.—On the 9th ult. The Orchid Club was inaugurated at Manchester with Mr. Fred. Hardy as President; Mr. F. J. Hanbury, the Hon H. D. McLaren, Mr. G. F. Moore, and Sir Edward Thomas Vice-Presidents; Mr. J. H. Walker, Treasurer; Mr. Bertram J. Beckton, Daisy Bank, Irlams-o'-th'-Height, Manchester, Hon. Secretary; and Dr. Craven Moore, Dr. R. N. Hartley, Mr. W. Morton Jackson and Mr F. T. Paul as members of Committee. Arrangements have been made to hold meetings in the Houldsworth Hall, Manchester, on December 14, 1923, and January 11, February 1, March 7, April 11, May 2 and June 6, 1924; the annual meeting will also be held on the last-named date. The objects of the Orchid Club include the promotion of a more intimate knowledge of Orchids, their natural history, morphology, cultivation and hybridisation, and the encouragement of investigation into the many interesting problems awaiting elucidation. The Committee will sit at 12 noon on the dates mentioned to adjudicate the merits of Orchids exhibited; the categories of awards will be (1) Premier Diploma; (2) Diploma of Merit; (3) Certificate of Cultural Commendation; and (4) Certificate of Commendation for instructional exhibits and demonstrations. Further, a special certificate or medal may be added to any of these awards to signify some exceptional and new feature, but only by the unanimous vote of the Committee. A meeting for the reading of communications and for discussion will take place at 3 o'clock on each meeting day. The annual subscription is two guineas for local members and one guinea for country members. We understand that the Manchester and North of England Orchid Society also will hold its meetings in Houldsworth Hall in the coming year on January 18, February 13 and 29, March 14 and 28, and April 25. If these two associations work together in harmony the cultivation of Orchids should receive a great impetus in the Manchester district.

Canada's Grain Harvest.—The average yield of Wheat in Canada this year is 20¾ bushels an acre, according to a second provisional estimate, compiled by the Dominion Bureau of Statistics. The estimate is based on the crop outlook on September 30. The wheat yield is approximately 3 bushels an acre higher than last year. All other grains show a considerable increase in this year's yield, Oats ranging on an average of 5 bushels an acre higher than in 1922. The total estimated crop for the year, in comparison with the 1922 crop, is as follows: Wheat, 469,761,000 bushels, against 399,786,400; Oats, 531,378,000 against 491,239,000; Barley, 80,357,000 against 71,865,300; Rye, 26,936,000 against 32,373,400; mixed grains, 29,090,000 against 27,707,700; Flax, 6,942,000 against 5,008,500. According to Canada the Wheat yield of the Prairie Provinces shows a heavy increase in the Alberta crop and a sharp drop in the yield of Manitoba, while Saskatchewan shows a slight increase. The total Wheat yield, by province, is as follows; Manitoba, 36,481,000 bushels; 1922, 60,0501,00. Saskatchewan, 252,622,000; 1922, 250,167,000. Alberta, 157,467,000; 1922, 64,976,000. Other Provinces, 23,191,000; 1922, 24,592,400.

Fewer Potatos.—According to the Agricultural Returns compiled by the Board of Agriculture, the total crop of Potatos in England and Wales this year is estimated at 2,756,000 tons, as compared with 4,012,000 tons last year, and 2,958,000 tons in the very dry year 1921. The average yield per acre in estimated at 5.9 tons, or 1¼ ton less than the very high figure of last year, and one-third of a ton below the average of the ten years, 1913-22. Yields are below the average in most counties, but of the chief Potato-growing districts Lancashire has the most unsatisfactory crops, the yield in that county being one ton below the average. In the Holland division of Lincolnshire and in Isle of Ely yields were only one-fifth of a ton below average.

Mr. Alexander McMillan.—Mr. McMillan, who retires during the present month after completing twenty-five years of service as head gardener to the Fulham Borough Council, has had an interesting career, his success proving the value of varied experience in different parts of the country, combined with a real love for his calling. Born at Newton Farm, Inverness, on February 15, 1849, he is the son of a farmer, who had eleven other sons. After leaving Inverness Grammar School at seventeen years of age he served three years in the extensive gardens of the late Sir W. G. Cumming at Altyre, near Forres. Thence he came to London. His first London experience was with Messrs. James Veitch & Sons, of Chelsea, after which he spent two years in the gardens of the Marquis of Zetland at Upleatham, near Saltburn, Yorkshire, and later, a similar period in the gardens of the late Marquis of Abergavenny at Eridge Castle, near Tunbridge Wells. For seventeen years he had charge of the extensive gardens at Oakley Park, Suffolk, first under the late Sir E. Kerrison, Bart., and afterwards under the latter's sister, the Rt. Hon. Lady Bateman. During this period he was a successful exhibitor of fruit, flowers and vegetables in Norfolk and

MR. ALEXANDER McMILLAN.

Suffolk, besides being a lecturer on Horticulture to the Suffolk County Council, travelling far and wide throughout the county. Leaving Oakley in 1896, he served for two or three years as lecturer and practical instructor in Horticulture to the London County Council. He was then appointed head gardener at Fulham by the old Vestry. When Mr. McMillan first went to Fulham, Bishop's Park, a tiny place, was the only public park there, but during the past twenty-five years it has been incresed to four times its original size, and another park has been laid out, besides a recreation ground. He also introduced glass, and being expert in plant culture he has made the Putney Bridge entrance to Bishop's Park a very pretty spot indeed, and one which always attracts people crossing the river from the Surrey side. One day this summer during Mr. McMillan's absence on duty, a motorist pulled up at the Putney Bridge entrance and was so enamoured of the beautiful flower beds and banks that he called a park attendant and voluntarily wrote on his visiting card: "I have been in all the London parks and this is the best of the lot." Mr. McMillan retires on a pension and regrets leaving his staff. He is settling down at Kew near the gardens "where," he writes, "I hope in my spare time to be a frequent visitor."

Bequests by the late Hon. N. C. Rothschild.—The will of the Hon. Nathaniel Charles Rothschild, J.P., of Ashton Wold, Oundle, Northampton, included several bequests of interest to gardeners. To the Royal Botanic Gardens, Kew, he left such of his collection of Orchids at Ashton Wold as were collected in New Guinea by Dr. A. F. R. Wollaston, or which represent Orchids so collected, and also any other specimens of his Orchids as may be desired as being of botanical, though not necessarily of horticultural, interest. He left his collection of Irises to his wife subject to selection therefrom by the Royal Botanic Gardens, Kew; the Edinburgh Botanic Garden; the Glasnevin Botanic Gardens, and the Cambridge Botanic Garden. The authorities of the various Herbaria at Kew, the British Museum, Oxford, Cambridge, Dublin and Edinburgh are also to have the opportunity of taking any specimens they may desire He bequeathed to the National Trust for Places of Historic Interest or Natural Beauty, whom failing, to the Society for the Promotion of Nature Reserves, his sporting rights over the Tring Reservoirs, the Fen and property in Angelsea Fen near Woodwalton, Huntingdonshire, and the Turf Farm and buildings (about 232 acres) adjoining, and if he shall have acquired it, the Ray Island property in Essex, together with a sum in the discretion of his executors, not exceeding £3,000, of which the income shall provide for the outgoings of the properties.

Appointments for the Ensuing Week—Monday, December 10: National Chrys. Soc. Floral and Executive Committees meet; United Hort. Benefit and Provident Society's meeting; Bath Gardeners' Society's meeting. Tuesday, December 11: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting. Wednesday, December 12: East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting. Thursday, December 13: Heathfield and District Horticultural Society's annual meeting; Wargrave and District Gardeners' Society's meeting.

"Gardeners' Chronicle" Seventy-five Years ago.—*Slate for Gardening Purposes.*—I have no hesitation in saying that slate is the best material that can be used for gardening purposes, such as for plant stages, slabs for Mushroom houses, hothouse floors etc., in the place of flags or bricks. Its chief recommendations are durability, neatness, efficiency, exemption from fungi, and from the accumulation of filth. It is a well-known fact that in houses where much humidity is required, bricks and flags often get covered with a species of fungus, the latter particularly, and to get rid of it is almost impossible, even though washing be practised every day. No such unsightly appearances occur in houses where slates are used; a rinse over now and then is all that is required, and they are clean. I am told that slate is in use at one of the principal London bridges for steps, where it has stood for more than three years without scarcely any apparent sign of wearing, even although thousands of people weekly pass over it. Nothing has been brought forward better adapted for tanks for holding water. In this point it deserves the highest praise and will prove a lasting benefit to those who use it. It is also valuable for tubs for large Orange trees or Rhododendrons. In the conservatory here are four beautiful specimens of Rhododendron arboreum, which are upwards of thirty years of age, two of them nearly as many feet in height, and are said to be the original seedlings from the Himalayas; they are flourishing luxuriantly in slate tubs. Slate is also extensively used in aquariums and with good effects. It deserves the attention of every lover of horticulture. *Robert Cox, Exotic Nursery, Gard Chron. December 2, 1848.*

BULB GARDEN.

A GOOD HARDY PANCRATIUM.

AMONGST the Pancratiums, of which there are several it cultivation, the hardiest undoubtedly is Pancratium illyricum, an attractive bulbous plant and one too seldom cultivated in the open garden. It would not be fair to assert that it would withstand the winters of many parts of the midlands and North of England and Scotland, but there are several mild districts, especially near the sea, where this plant would flourish and increase. It is a good plant in every respect, sending up from among its attractive leaves a stout stem which bears at its summit a number of fair-sized white flowers. These, in addition to the beauty of their form and colour, are also deliciously fragrant.

This species is considerably hardier than P. maritimum or P. littorale, which are probably more resistant to our winters than most others, but even these cannot be reckoned worth growing in the open, because of their tenderness. On the contrary, P. illyricum does not always even require the covering of litter or ashes which is recommended for it.

Planted about six inches deep in light, loamy, well-drained soil it will withstand the severity of an average winter, in all seaside districts at least. I know of one famous Scottish garden where this Pancratium has been established in the open for years, and where it receives no protection whatever. It is best planted as soon as the leaves decay in autumn. Offsets may be taken off at that time, and some recommend lifting and replanting the bulbs every three or four years, yet this seems unnecessary where they are doing well.

ALLIUM TRIQUETRUM.

GARLICS, beautiful as many of them are, never gain high favour in the garden. The odour which some of them possess and emit in a pronounced way, is not agreeable in the garden. Yet, the Alliums include some pretty plants, a proportion of which are not so lavish with their odour as to be offensive. This is true of Allium triquetrum, which in the garden is practically odourless, except when touched or bruised. It is not a plant that one would commend for cutting for the home, pretty as it looks when in a small vase.

It is of most value in groups in the border or large rock garden, while it has also been employed with advantage in grass and in the wild garden.

The plant grows about one foot high, more or less, according to the nature of the soil, and has rather pretty and curious triangular stems, and drooping white flowers in considerable numbers.

This Allium increases fairly freely from self-sown seeds and offsets, but is not so pervasive as some of its allies. Bulbs may still be procured and planted at a depth of about two inches. The plant will thrive in sun or shade, and is not fastidious as to the nature of the soil, being satisfied with any medium of reasonable texture. *S. Arnott.*

THE CHINKERICHEE.

RARELY does a year pass without one or more spikes of the Chinkerichee arriving at the offices of the *Gard. Chron.* Usually the spikes are sent by some visitor to South Africa to a friend in the British Isles, and the latter sends along a specimen for identification, accompanied by an expression of wonderment that flowers so beautiful should survive the long journey in a postal package and that new flowers should appear on the spikes for a considerable period when the stems have been newly cut and placed in water. In most instances the flowers are those of the Chinkerichee — Ornithogalum thyrsoides — but sometimes spikes of O. lacteum are received. On occasion baskets of these Ornithogalum flowers have been exported from South Africa, and during the past week at least one salesman in Covent Garden has exposed such flowers for sale.

At the meeting of the Royal Horticultural Society, held at Vincent Square on November 13, Miss I. E. Wright, of Kayhough, Kew, exhibited a bowl of flowers of O. thyrsoides and O. lacteum; she received the spikes from South Africa on October 22, after they had experienced a voyage of three weeks in cold storage. The accompanying illustration (Fig. 119) is from a photograph of these same flowers taken on November 21, when they were still fresh and appeared to be well able to continue in good condition for some time to come. Both O. thyrsoides and O. lacteum are in cultivation in this country, and though not often seen there are obvious and good reasons why the cultivation of these bulbous plants should be taken up by amateurs. Although the popular title of Star of Bethlehem is usually assigned to Ornithogalum nutans, this name is also applied to O. thyrsoides in South Africa. Yet another title is that of Viooltje, but this is not so commonly used as Chinkerichee, which is but a slight variant on the "Tinterintjes" of Thunberg's time.

FIG. 119.—SPIKES OF ORNITHOGALUM THYRSOIDES AND O. LACTEUM IMPORTED FROM SOUTH AFRICA.

THE ROSE GARDEN.

INTERESTING ROSES IN A UNIVERSITY GARDEN.

THE Annual Report of the Botanic Garden Syndicate, Cambridge, states that Major C. C. Hurst during 1922-1923 has been doing research on the genetics and cytology of Rosa. He has found a number of distinct forms in the Botanic Garden. Two of these are apparently new to science, and several seem to be the original types of specimens of Lindley and others. Of the two new forms one is a pentamerous R. sericea Lindl., from the Western Himalayas. It differs from the ordinary forms in having, as a rule, five petals and sepals instead of the four peculiar to the species of the section Sericeae, Crepin. Genetically this is an interesting example of meristic reversion to the ordinary type of the species of the other sections of Rosa. Steps have been taken to "bag and self" a number of flowers of this plant in order to ascertain its genetic composition. This plant is growing at the north-west entrance of the rock garden, and has been named provisionally R. sericea, Lindl., f. pentamera. The other new form is apparently a spontaneous hybrid between the Himalayan R. sericea, Lindl., and the Chinese R. Hugonis, Hemsl. This hybrid has the yellow and pentamerous flowers of R. Hugonis with the habit of growth and the glandular leaves of R. sericea. A detailed analysis of 50 taxonomic characters of the hybrid shows the dominance of R. Hugonis in 23 and the dominance of R. sericea in 19. The remaining 8 characters are intermediate between the presumed parents. The hybrid was found growing in the middle of an extraordinary free-flowering bush of the Himalayan R. sericea, Lindl., which on account of its habit Major Hurst has distinguished as R. sericea, Lindl., f. floribunda. This bush is growing in the middle of the collection of Rosa species, between the Middle Walk and the east side of the Pond. In view of the position of the hybrid, it is not unlikely that R. sericea floribunda was the mother parent. The presumed father parent, R. Hugonis, is growing a few yards away. This year it was observed that at the time these two species were in flower together, they were constantly visited by the larger kinds of bees, so that there was every facility for cross-fertilisation. In order to test the postulated parentage of this hybrid crosses between these two species have been made artificially, both ways. Attempts have also been made to breed the F_2 of this hybrid by selfing and back-crossing it with its presumed parents, which, if successful, should yield results of genetic importance. It is proposed to name this new hybrid R. cantabrigiensis. If the above parentage is confirmed experimentally the hybrid will be not only a specific one between R. sericea, Lindl., and R. Hugonis, Hemsl., but also a sectional hybrid between Sericeae, Crepin and Pimpinellifoliae, DC.

THE BEST ROSES IN AMERICA.

ONE of the largest growers of Roses in America for cut blooms considers the variety Premier the most profitable and grows 100,000 plants of it. Columbia comes next, and Mme. Butterfly third in quantity, 75,000 plants of the former being grown. Milady and Crusader are the red sorts cultivated by this firm, whilst of white varieties White Killarney and White Ophelia are grown, the latter proving very good. Mrs. Aaron Ward, Phantom and Cecile Brunner are varieties cultivated for their small flowers.

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Cypripedium.—Many plants of this most useful genera are past, or nearly past, their flowering period, and the plants, unlike those of other families of Orchids, may be repotted at any season. Those that require repotting should be attended to as soon as possible, and one of the first to be done is the lovely Cypripedium insigne Sanderæ. Those plants, the stock of which it is desired to increase by division, should have the old material carefully picked out, to see where the rhizome may be best cut through. Care should be taken with the roots, but even with the greatest care some will be broken. Plants that are not to be divided may be potted on, should their centres be quite sound and well filled up, but if the centres are weak they should be picked to pieces, the old dead rhizome cut away, the portions placed together again and potted in the same-sized pot. I do not favour the use of too much loam for these Orchids, as I find they develop more freely and produce finer flowers when grown in a more open compost. The rooting-medium I recommend for green-leaved Cypripediums consists of equal parts peat and A.I. fibre, with live Sphagnum Moss, well mixed together, with a small quantity of the best fibrous loam carefully placed in the lower layers; if it is placed near the surface the loam is likely to become dry and hard. These plants, unlike many Orchids, require a reasonable amount of pot room, and are so easily grown that they are to be recommended to anyone who can give them the requisite temperature. Cypripedium plants that have been newly potted should be thoroughly cleansed, placed at a warmer end of the house, and watered with extreme care. The compost for potting should be neither too wet nor too dry, and should be warmed to the same temperature as the house before it is used. Light sprayings overhead will be beneficial to the plants on all favourable occasions, and assist them greatly in becoming re-established.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Wolverstone Park Gardens, Ipswich.

Early Vines.—Where it is desired to have ripe grapes in May, the vinery should be closed forthwith, if the necessary work of pruning, etc., has been completed. If this has been done no further operations are required beyond examining the borders to ascertain if they require soaking, and if so give the soil a good watering with clear water warmed to about 80°. In the early stage the vines should not be unduly forced; a night temperature of 50°, and a day temperature of 55° to 58° will suffice until the buds are swelling freely, when both the night and day temperatures may be a few degrees higher. Thoroughly damp the rods once or twice daily according to the weather, and promote a moderately moist atmosphere by damping the paths and other bare spaces. Admit air when the weather is favourable, to sweeten the atmosphere of the house. When the buds are swelling freely and evenly the young canes which have been tied down should be attached to the trellis. If the borders are out-of-doors they should be covered, preferably, with mild fermenting materials, and this in turn should be covered with spare lights, wood shutters, or other material, as a protection against snow and rain. Failing this, cover the border with a thick layer of Oak or Beech leaves, and on top of the leaves place a few inches of long stable litter, or dried Bracken Fern, to prevent the leaves from being blown away.

Strawberries.—If early berries are required, a batch of plants should be started this month. In most cases, a special Strawberry house is out of the question; an early vinery just started is, however, suitable for the purpose. If there is a mild hot-bed in the house the plants may be placed over it, preferably on trellis-work as, by leaving a space between the fermenting material and the pots, there is less danger of the plants being unduly hastened into growth. It is essential that growth should be steadily maintained from the start to obtain stout, healthy foliage and strong flower spikes. As soon as growth becomes active, the plants should be removed to a position near the roof-glass, either in an early vinery or early Peach house. Before taking the plants indoors remove any partially-dead leaves, mossy growth, and weeds. It is advisable to dip the foliage in an insecticide. Ram the soil firmly around the edge of the pots, if it is not too wet, otherwise defer the operation until the soil is in a more suitable condition. Ascertain that the drainage is perfect and, if worms are troublesome, water the soil with clear lime-water; this will clear out the worms and benefit the plants at the same time. Watering should be done with great care during the early stage of forcing.

THE FLOWER GARDEN.

By C. TURNER, Gardener to EMILY, LADY AMPTHILL Ampthill Park, Ampthill, Bedfordshire.

Helleborus niger.—Where the flowers of this plant are appreciated for indoor use the old-time plan of covering a few clumps with glass to keep the flowers clean should be adopted. In the case of a few odd plants, a large piece of glass fitted in niches cut in four strong sticks and arranged over the clumps will suffice, but requirements on a larger scale are best met by placing a hand-light or movable frame over several roots. Fresh air circulating about the plants is necessary at all times, except in frost-bound days. The Christmas Rose responds well to gentle forcing but lifting and forcing the plants is unnecessary if the method described above is followed. A good place for planting Helleborus is among hardy Ferns under the shade of trees, the lower branches of which have been removed so that the shade is not too dense.

Fruiting Crabs.—Notwithstanding the great ornamental value of these trees, their merits do not meet with the recognition in gardens which is their due. In my opinion the decorative value of the flowers in spring and of the fruits in autumn easily eclipse that of some of the more widely-planted flowering shrubs. These Crabs are equally free in fruiting as in flowering, and the inclusion of a few specimens in any garden cannot be other than a perennial source of pleasure, and also of utility if the fruits are used for the making of Crab-Apple jelly. The planting of these trees may be done now, and an open space in the woodland or pleasure ground, or the back of large flower borders suggest themselves as suitable sites for planting. The varieties John Downie and Dartmouth should be included in a collection of the best sorts.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Stephanotis floribunda.—Where this sweet-scented climber is grown the present is a suitable time to thin the plant of weak or old shoots that are not required. At the same time cleanse the plant thoroughly if it is infested with mealy bug.

Clivia.—Plants of Clivia that have been kept in a cool house and fairly dry at the root, will now respond to gentle warmth. A portion of the stock may be placed in a house having a temperature of 55° to 60°, giving the plants more water at the roots than hitherto. Well established plants with plenty of roots will be benefited by frequent applications of diluted liquid manure or soot water. Clivias succeed very well planted out in beds or borders in a cool conservatory.

Eucharis grandiflora (syn. amazonica).—This beautiful stove plant was at one time common in gardens, but is now seldom cultivated. Plants that have been rested in a house having a low temperature and kept somewhat dry at the roots, may now be introduced to a warm house, affording them more water at the roots, and, if possible, plunging the pots in a hot-bed. This plant needs a very warm temperature, but at this season 65° to 70° is sufficient warmth. When in good condition the Eucharis should be fed liberally with liquid manure, which will give strength and substance to the flower scapes. This plant is often reputed to be difficult to cultivate successfully; failure is usually due to exhaustion by over-flowering and drying off the plants too severely. The plant is an evergreen, and if a rest is considered necessary, it is best given by keeping the plants slightly dryer at the roots and growing them in a slightly lower temperature. The Eucharis succeeds very well when planted out in beds, with bottom heat at command. They are subject to attacks of mealy bug and thrips, and should be kept clean of these pests by sponging them on frequent occasions. Other beautiful and desirable species are E. candida, E. Sanderi, E. subdentata and the hybrid E. Stevensii.

Hydrangea paniculata var. grandiflora.—This hardy Hydrangea is very useful for growing in pots, as it may be had in flower during the late spring and early summer. To obtain the best results, young, strong-growing plants are essential. They should be potted forthwith to allow time for them to become established at the roots before they are taken indoors for forcing. After potting they should be stood out-of-doors, plunging the pots to their rims in ashes or packing around them with hay. As the plants produce their flowers on the ends of the current year's growth, they should be pruned hard back when they are introduced to the forcing house. They are best brought on slowly in an intermediate temperature of about 50°.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Asparagus.—This vegetable forces readily, and, although the stems are not so good flavoured as those cut from the open beds, they are very acceptable at a time when fresh vegetables are scarce. Heated frames may be used for the purpose, if desired, but frames over hot-beds made of leaves and stable litter are preferable, as the warmth from these fermenting materials is accompanied by plenty of moisture. The materials should be well mixed, two parts of leaves to one of litter, and well trodden as the bed is formed. Allow a space of about two feet around the outsides of the frames in order to have room for placing fresh manure and leaves as linings to conserve the heat. Place a little rough material in the frames, and, on this, spread three or four inches of old potting soil mixed with fresh loam, and then place the Asparagus roots evenly all over the surface, just touching each other. Cover the plants with about four inches of fine soil and press them down lightly. Water the plants with tepid water, using a rosed can, then place the lights in position, and keep the frame close except on bright mornings when a little air should be admitted. The warmth from the bed should be allowed to decline before placing the crowns on the soil. The condition of the hot-bed may be determined by using a plunging thermometer, or a stick will answer the purpose. If examined every day, one may soon determine when it will be safe to plant. Very little moisture will be needed by this method of forcing, but if a heated frame is employed, it will be advisable to damp the surface of the bed with a syringe each afternoon, and especially in parts near to the water pipes.

Digitized by Google

Plants in Frames.—Attend closely to Lettuces and Endive growing in frames, admitting air on all possible occasions. Damp will do most damage now, therefore do not water the plants unless moisture is necessary, and then only on bright mornings when the weather is not excessively cold. Even in severe weather, a little air should be admitted some time during the day to counteract excessive damp. Autumn-sown Cauliflowers that are being wintered in frames should be well protected in the event of severe frosts, and given air whenever possible. Keep the surface soil stirred between the plants, and water the plants sparingly.

General Remarks.—Endeavour to get as much ground dug or trenched as weather permits, as it is very helpful to have so much of this kind of work done as possible before the New Year. In frosty weather ground to be trenched may be covered with a good thickness of stable litter to prevent it becoming too hard to dig. On no account should snow be dug in. In bad weather much may be done to relieve pressure of work later. Pea and Bean sticks may be sharpened and sorted into different lengths; labels of different sizes made, and all tools examined and well cleaned and greased. Each member of the staff should have his own tools, and be responsible for their proper upkeep. Boxes may be made for pricking out seedling vegetables.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

The Training of Fruit Trees.—Fan-trained trees are usually of three types, those having a stem 5 feet to 6 feet tall, or they may have stems 3 feet high, and those which have radiating shoots starting about 1 foot from the ground. Peaches, Apricots, Plums, Cherries and Nectarines are trained in this form. Espalier, or horizontally trained trees, may also have a long stem with three or more tiers of shoots trained horizontally; cordons may have from one to five main stems. These, and especially the toasting-fork type, are very useful for growing on wire fences. The oblique single cordon is also useful for this purpose; Pears are often grown under this system of training. In gardens of restricted areas espalier and cordon Apple and Pear trees are the most useful, and these types of trees are valuable in larger gardens for growing on walls and fences. In large gardens the bulk of the Apple trees should be of bush form in a plantation by themselves and not dotted over the garden. The gridiron or fork-shaped method of training is suitable in the case of Gooseberries and Currants when trained on walls. The usual distance at which Apples and Pears are planted is 12 feet by 12 feet, but for Apple Blenheim Pippin the distance should be increased. If on the crab stock, large-growing varieties should have a distance of 18 feet by 18 feet. These may include Bramley's Seedling, Newton Wonder, Bismarck, Warner's King, Prince Albert and Lord Grosvenor. If Cherries are grown in bush form, the trees should be planted together where protection from birds, in some form, can be provided. Pyramidal-shaped trees are not often planted; this style is usually adopted in the case of Pears. Figs are usually fan-trained, and are only suitable for growing on warm walls. Notwithstanding Figs will grow in almost any kind of soil, the ground should not be very rich or the trees will make too much wood growth. The rooting medium for Figs should be restricted and the soil about their roots made very firm. The object is to obtain short-jointed, well-ripened shoots.

Orchard Trees.—Orchard trees are usually of standard form. Their pruning consists in thinning out the branches, to let in air and light; all growths that cross others should also be removed, and all saw cuts pared smooth with a sharp knife and the surface painted with gas tar. The removal of large trees with a ball of soil may be undertaken at any time when the weather is open.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM BERYL.

MR. W. J. STABLES, gardener to Clive Cookson, Esq., Nether Warden, Hexham-on-Tyne, sends a flower of this beautiful cross between O. Uro-Skinneri splendens and O. Amethyst, flowering on a plant acquired at the dispersal of Mr. Phillip's seedlings. It was first flowered and named by Messrs. Charlesworth & Co. The flower, which adheres closely to the O. Uro-Skinneri parent, but is on a much larger scale and darker in colour, has the sepals heavily blotched with dark claret-purple, the petals being densely spotted with a lighter tint. The broad front of the lip, which is circular in outline, has a white ground closely spotted, like the petals, with mauve-purple, the base having a prominent yellow crest on a purple ground. The column is white with purple markings. It is one of the darkest and best of the O. Uro-Skinneri crosses.

ODONTOGLOSSUM CRISPINDIA.

C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), sends a first flower of a cross between O. crispum var. Rossendale and O. Empress of India, which promises to develop into a very distinct, large-flowered Odontoglossum of the lighter-coloured section. The flower is nearest to the crispum parent; the ground is white with red blotches and a cluster of purplish lines in the middle of the petals. The lip is white, crimped at the margin and has rose-purple spots round the yellow crest.

MEMORIAL TO SIR ISAAC BAYLEY BALFOUR.

DURING his thirty-four years' tenure of the office of Regius Keeper of the Royal Botanic Garden at Edinburgh, the late Sir Isaac Bayley Balfour won the respect and regard of so many individuals that a spontaneous desire to honour his memory made itself evident soon after his death.

As often happens at such times, suggestions were mooted for memorials of various kinds, and there were not a few who felt that the Edinburgh Botanic Garden itself afforded as appropriate a monument as could be found to the distinguished savant who made it what it is to-day. As, however, there are obvious difficulties in permanently linking the name of a particular Director with a National Garden, some other form of memorial had to be sought. Proposals were made for an architectural monument to be placed in the Inverleith Garden; for a triennial lectureship on the lines of the Masters Memorial Lecture Fund, administered by the Royal Horticultural Society; and for the foundation of a scholarship at Edinburgh University.

Sir Isaac Balfour's views on the subject of architectural monuments precluded the adoption of any proposal of the kind, and it seemed doubtful if either of the other proposals would be of sufficiently tangible character to command wide support. In these circumstances, a happy solution of the difficulty has been proposed by some of Sir Isaacs' friends, and the more appropriately, because it will bring to fruition a scheme he himself suggested some years ago. It is nothing less than the enclosure and consecration to Sir Isaac Balfour's memory of an area in a wild but accessible district, where the natural Orders of plants in which he was more particularly interested, may be grown in a natural way. Sir Isaac's interest in the botanical explorations which have been going on in Western China and the confines of Tibet for more than twenty years, and the brilliant service he rendered to botanical science and practical horticulture in the enumeration and classification of the results of those explorations are well known; but it is not so well known that several years ago, when he realised the almost illimitable extent of the mountain flora of Western China and particularly of the Rhododendron genus, which was—and still is—in process of discovery, Sir Isaac conceived the idea of forming a plant sanctuary or reserve in some district where the flora in question could be grown under wild conditions, not, of course, approximating to those of their native land—for that is impossible—but as favourable to them as we can hope for in Great Britain.

Sir Isaac realised better than most the limitations of space, climate, and soil imposed upon the cultivators at the Inverleith Garden, and was aware that there are areas on the west side of Scotland where those limitations are profoundly modified, even if they exist at all. When he first conceived the idea, the pre-occupations of the War compelled him to lay it aside, but it was seldom out of his mind, and some years ago he revived the project and had gone so far on the road towards the execution of it, as to examine the suitability of more than one area, and to interest a few friends in it.

By that time, however, his over-taxed strength was failing him and he found himself unable to take further official part in the scheme. But the seed he had sown bore fruit, and though he never lived to see the fulfilment of the project he had so much at heart, it gave him unfeigned satisfaction to learn from the Forestry Commission, soon after his retirement, that subject to arrangement with the Office of Works, the Department responsible for the administration of the Edinburgh Botanic Garden, the Commissioners proposed to place at the disposal of his successor an area in Glenbranter Forest which it was thought would meet the requirements he had laid down. It is this area, which, thanks to a happy inspiration, it is now proposed to dedicate to Sir Isaac Bayley Balfour's memory. To the end Sir Isaac took a keen interest in the Commissioners' plan, and assuredly nothing could have pleased him more than to know that his suggestion of a sanctuary for Western Chinese plants was about to be carried out.

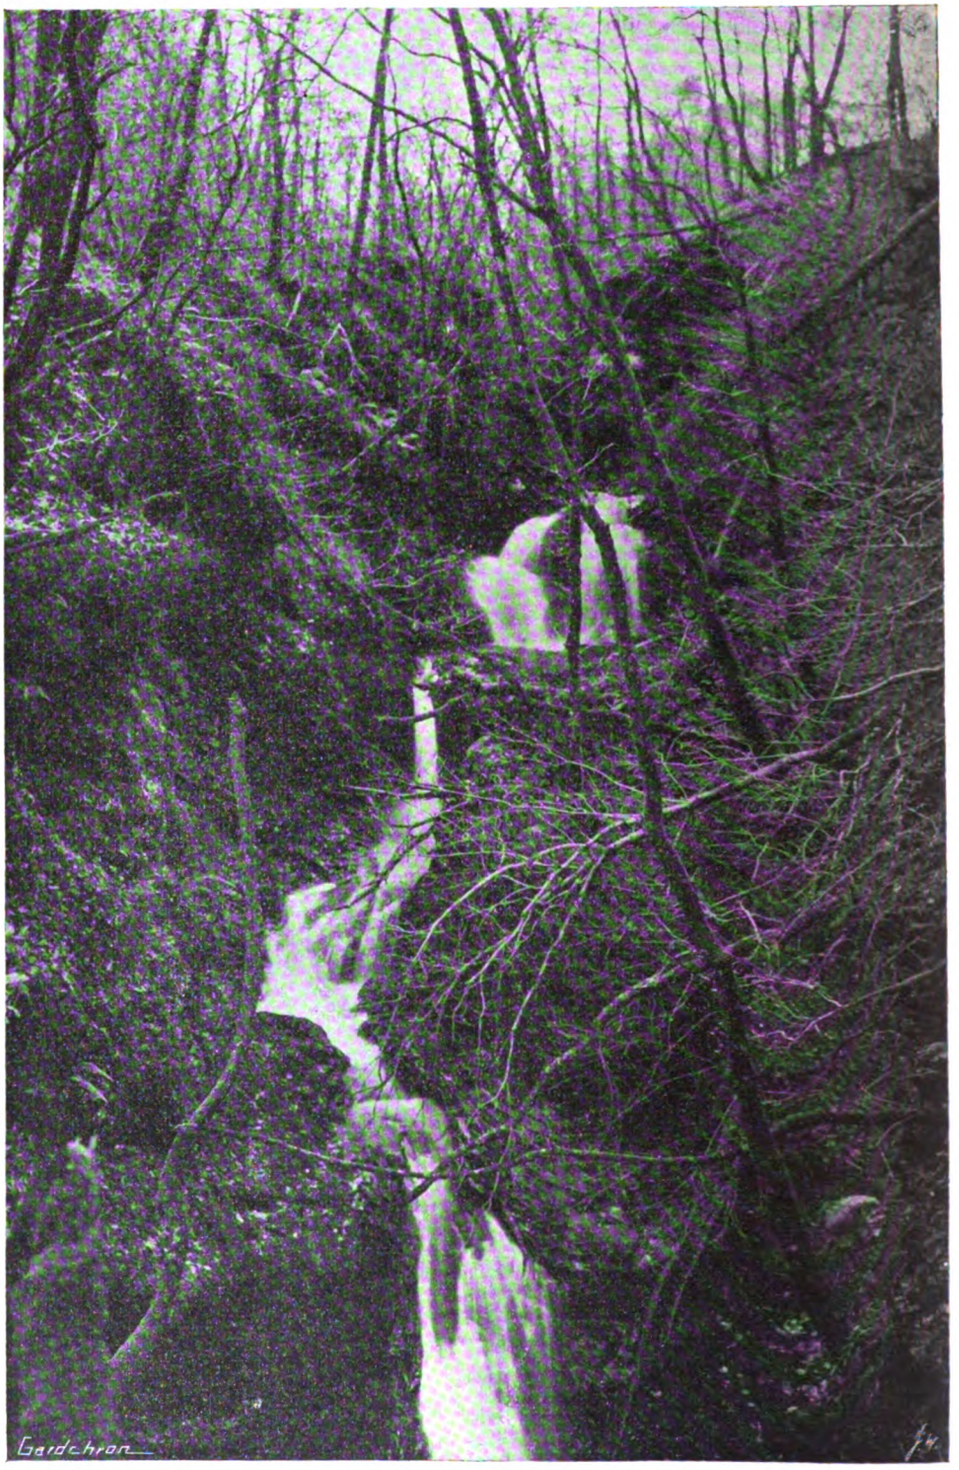

FIG. 121. THE BURN IN THE BAYLEY BALFOUR MEMORIAL GARDEN AT GLENBRANTER.

Sir Isaac always held that the Reservation, as we may call it, should be worked in conjunction with the Edinburgh Botanic Garden, the latter being drawn upon for the raw material in the shape of plants and the skilled superintendence necessary for their arrangement, planting, etc. The Reservation in turn would provide the Regius Keeper and the Forestry Commission with a valuable testing ground, and at the same time furnish students and the cause of botany and horti-

culture in general with first-hand information such as could hardly be obtained elsewhere in Great Britain, at any rate, in a ring fence.

It is satisfactory to know that Sir Isaac's successor in the office of Regius Keeper, Professor Wright Smith, considers that the proposed site of the Bayley Balfour Memorial Garden is admirably adapted to the purpose, and that his opinion is shared by Sir Isaac's old pupil, Mr. George Forrest, whose epoch making pioneer work in Western China will provide Glenbranter with material for years to come.

The total acreage of the area it is proposed to allocate to the Memorial is about fifty. In one part of it, a burn has cut for itself a gorge through which the water cascades into boiling "cauldrons" (Fig. 121). On each side of the gorge is a thin Oak wood (Fig. 120), providing an ideal situation for many of the Chinese Rhododendrons, and there could hardly be a more happy home than the banks of the

FIG. 122. GLENBRANTER: VIEW FROM THE UPPER PART OF THE BAYLEY BALFOUR MEMORIAL GARDEN, LOOKING SOUTH, ACROSS GLEN SHELLISH, TO BEINN BHEAG (2,029 FEET).

burn for many of the Primula family of which Sir Isaac Balfour was master. The ground is true forest soil, with a generous accumulation of humus; and here and there deposits of peat. The climate has the mild humidity so characteristic of the atmosphere of the west coast of Scotland, and frosts are rare. As is clear from the accompanying reproductions of splendid photographs made by Sir John Maxwell, who has done so much to bring the Memorial garden into shape, Glenbranter is set amid magnificent scenery (Fig. 122), and it would be difficult to find a site more entirely appropriate to the objects Sir Isaac Balfour had in view.

Glenbranter is about fifteen miles north of Dunoon on the Clyde; it is between Loch Goil and Loch Fyne, and lies a little to the north-west of Loch Eck. It is easily reached from Dunoon, or one can go to it by road from Glasgow via Arrochar, at the head of Loch Long.

It is hoped to erect a modest rest-house for the use of students and others interested in the genera growing in the area, to furnish it with a small library of botanical books of reference and to place in it a simple memorial tablet to Sir Isaac Bayley Balfour.

Sir Isaac Balfour probably did more than any other man of his generation in the cause of botany and horticulture. His Masters Memorial Lecture, "Some Problems of Propagation"—a classic of its kind—has brought light to many who were groping in the dark over the interesting problems the author illuminated in his famous paper. His insistence on the principle that it is the duty of the director of a national garden to assist the practice of horticulture to the best of his power, and his broad-minded application of the principle during his reign at the Edinburgh Botanic Gardens, were of immense practical service to professional and amateur gardeners all over the country. A more generous giver could hardly be conceived, nor a more accessible holder of a public office. There can hardly be many persons seriously interested in botany or horticulture who, at one time or another, have not derived pleasure or benefit from Sir Isaac Balfour's work. They will assuredly welcome the opportunity of paying a tribute to his memory by helping on what is certainly the most appropriate kind of memorial imaginable—Glenbranter.

DR. GORDON OF BIRNIE.

THE *Northern Scot and Morayshire Express* for April 20 of this year contained an account of a dedication ceremony held in the Birnie Parish Church, for the purpose of perpetuating the memory of the late Rev. George Gordon, LL.D. Students of botany interested in the flora of the northern counties of Scotland will remember Dr. Gordon as the author and compiler of a little book of some fifty pages, popularly known as the *Flora of Moray*, but having on its title page the following inscription. "Collectanea for a Flora of Moray; or a List of the Phænogamous Plants and Ferns hitherto Found Within the Provence. Elgin. Printed by Alex. Russell, Courant Office, 1839."

The Horticultural Directory and Year Book for 1923, refers to the time when this Flora appeared as "the dawn of what is commonly termed the scientific age," and we have only to read the following paragraph from the descriptive preface, written perhaps twenty years before Charles Darwin's name was publicly identified with the science of evolution, to admit that Dr. Gordon already understood tha environment had some definite influence on the origin of species:—

Dr. Gordon is dealing with the Meadow Oat-grass, and writes, "In a few spots within the Provence such as Craighelkie, near Gominloul, where the beds of limestone subordinate to the primary stratified formations crops out, there is occasionally to be found several species of plants whose range is evidently circumscribed within the influence of the calcareous soil. Avena pratensis seems confined to soils of this nature, changing its habit as the proportion of their ingredients differs; where there is a superabundance of limy matter the plant often assumes a glaucous and rigid appearance, which has probably originated the A. alpina, and causes it still to hold a place as a distinct species."

There are 724 species in the catalogue of Moray plants, of which "sixty-five are doubtfully native and seventy certainly introduced." Arranged in the artificial classification of Linnaeus, the system then in use, but as showing that botanical taxonomy was undergoing a change, they apperr further on in the book generically grouped in almost the same sequence as in the Natural System of the present day.

In 1839 there were growing in Morayshire the following plants of interest to horticulture:—at the Castle of Old Duffus, Parietaria

Digitized by Google

officinalis, Anchusa sempervirens, Berberis vulgaris, Prunus domestica, Arum maculatum; Humulus Lupulus and Scolopendrium vulgare, Elgin Cathedral had Verbasum Thapsus; Cheiranthus Cheiri, and Malva rotundifolia, at Spynie Castle were Hordeum murinum; at Pluscarden Priory, Papaver somniferum; at Kinloss Abbey, Atropa Belladona; at Drainie Manse was Datura Stramonium and in the Churchyard Carduus acanthoides; on a wall near Greyfriars, Elgin, was Sedum reflexum; at Innes House grew Euonymus europaeus, and at Gordon Castle and its vicinity, Ligustrum vulgare, Epimedium alpinum, Pulmonaria officinalis, Symphytum tuberosum, Galanthus nivalis, Narcissus Pseudo-Narcissus, Convallaria majalis and C. multiflora, Spiraea salicifolia, Meconopsis cambrica, Hieracium aurantiacum, Euphorbia dulcis, and Salix Russelliana, and on the garden wall Linaria Cymbalaria. The "doubtfully native" but highly-poisonous Conium maculatum was common in the churchyards of Spynie, Duffus, and Drainie.

As showing the interest taken in what might be called practical field botany, of the thirty or so names of those associated with Dr. Gordon and who are given credit for collecting particular species, ten of them were men of university education, seven ministers, and two doctors. With his personal knowledge of the climate, he claimed that "In Moray there are examples of all the Regions described in the *Geography of British Plants*, whether tested by its temperature or its plants (indigenous or exotic)." In his opinion, the Flat, or How, of Moray is in every sense the "Region of the Plains," and, no doubt, it is this same "Region" to which a correspondent of *The Gardeners' Chronicle* of July 28 refers when he singles out the Moray Firth as one of the "relatively mild" and "specially favoured districts" of the east Coast of Britain.

At the dedication service referred to, a brief reference was made to Dr. Gordon's high standing in the field of science, and it has occurred to me that readers of *The Gardeners' Chronicle* might be interested in him and this little book which has now seen eighty-five years of useful service. *George Fraser, Ucluelet, British Columbia, Canada.*

INDOOR PLANTS.

THREE GOOD COOL GREENHOUSE CLIMBERS.

I have often been asked for a list of the best climbers for a cool greenhouse or conservatory. There are few plants that are sufficiently robust to withstand the deleterious atmosphere in gardens in close proximity to large towns, yet a few evergreen climbers are suitable for the purpose. These are grown for their foliage alone, and may be highly recommended provided the temperature of the house does not fall below 35° to 40° in winter. Amongst them is Vitis (syn. Cissus) antarctica, and Vitis (syn. Cissus) rhombifolia. Although now classed with Vitis, Cissus is the title best known to most gardeners. There are not many species of Cissus that have any pretension to beauty suitable for cool treatment or for decorative purposes with the exception of the two mentioned. C. discolor, a free growing species with purplish leaves that are beautifully marked with white, and shaded pink, needs a stove temperature, and is not a success in a cool house. These two cool-house species were in great demand during the seventies and eighties of the last century and were grown largely for decorative purposes, for furnishing the pillars and rafters of cool greenhouses. They were also much used for house decoration, for screening fire-places, etc., as the foliage remains fresh and bright over a very long time, but of late years they seem almost to be lost to cultivation and forgotten. They are both of the easiest culture and cuttings formed of half-ripened shoots root freely in a hand-light or frame with slight bottom heat. During the summer the plants may be grown with scarcely any fire-heat; they should be kept shaded from the bright rays of the sun, and given plenty of moisture. As pot specimens they make useful decorative plants, and when planted out they grow so freely as to soon cover bare walls and pillars of cool greenhouses. There are few evergreen climbers more suitable for withstanding fogs. C. antarctica is a most useful species; it is a quick-growing, ornamental, evergreen climber or twiner. C. rhombifolia is distinct from C. antarctica; the trifoliate leaves are dark green and of graceful habit; it is a fine decorative plant and most distinct. Both species are admirably adapted for situations where vigorous climbers are required. The flowers on each are inconspicuous. Both may be grown into handsome specimen plants by placing two to three plants in a large receptacle and training the shoots upright on strong sticks or poles; they will soon form good specimens and may be placed in any vacant position with good effect either in the conservatory or dwelling house. The most suitable soil for these plants is a mixture of good turfy loam, leaf mould or fibrous peat, and silver sand added. Both species are quite exceptionately immune to attacks by insects. Syringing them two or three times daily is beneficial during the summer. When well rooted and growing freely the plants need liberal supplies of water, and plenty of drainage should be provided to prevent the soil becoming sour.

Another beautiful evergreen climber not often met with at the present day is Ruscus androgynus. This is an elegant, quick-growing climber, most suitable for growing in a large greenhouse or conservatory, and one of the most useful plants for covering rafters and roofs of a large house. It forms masses of lustrous, bright green foliage, and is of rapid growth, especially when planted out in a cool, moist part of the house and kept shaded from the direct rays of the sun. When planted permanently in a large house, strong specimens should be selected and set in a hole 3 feet to 4 feet across and about 3 feet deep, with plenty of drainage material in the bottom of the hole. Remove the unsuitable soil and substitute a mixture of good, turfy loam and fibrous peat or leaf mould in equal parts with silver sand added; manure is not necessary. The plant does well if afforded similar treatment to that given to Lapageria rosea. The error of deep planting should be guarded against. Cover the crown of the plant with about 3 inches to 4 inches of soil, and water the roots freely during the summer, when the plant has started into growth. A beautiful specimen of this plant grew for many years in the corridor to the King's Road entrance to the Royal Exotic Nursery, Chelsea, against the wall in a shady position, and was the admiration of visitors on account of its neat growth and dark green foliage. The plant was given very little attention, and often during the winter the temperature of the corridor fell to freezing point. The plant produces its flowers and fruits on the leaf-like expansions of the stem. It thrives fairly well out-of-doors in warm and sheltered situations where it is protected from severe frost. *John Heal, V.M.H.*

BIGNONIA GRANDIFLORA.

This plant (see page 273), is quite hardy on a south wall as far north as Belvoir Castle, Grantham, but it does not flower there every year. Like some other flowering shrubs, this Bignonia flowers on wood of the current year's growth, which needs to be produced early and well ripened. There are many places south of London where it would succeed in warm summers. The finest plant I have seen was growing at Andover, in the hot and dry summer of 1921. It was trained roughly over an old shed and was nearly twenty feet across. The roots were restricted but were near the bed of a stream and had not suffered from the drought. The plant was almost covered with the beautiful flowers and formed one of the finest specimens of flowering shrubs I have seen. *W. H. Divers, V.M.H.*

HARDY FLOWER BORDER.

THE CHRISTMAS ROSE.

Although Helleborus niger is perfectly hardy it is best to give the plant a little protection before the flowers open. This may take the form of a cold frame placed over the plant and the lights may be placed in position when much rain or frost is expected. A single plant may be covered with a bottomless box, with a sheet of glass placed on the top of the box each night; and in very cold weather a mat should be used, removing this early the following morning.

The Christmas Rose resents root disturbance, but where there is ample stock a few plants may be potted in November to produce extra fine flowers for Christmas decoration. After these pot plants have flowered they may be broken into pieces with about three leaves attached to each to increase the stock. Planted eighteen inches apart each way, they will grow into large clumps.

The Christmas Rose requires a deep, rich, loamy soil, and one containing plenty of leaf-mould and well-decayed manure. It always pays to form a special bed on the north side of a hedge or wall that may be covered easily with a frame or handlight in winter.

The plants are also very effective in clumps in a sheltered part of the garden, or when grown in woodland borders.

They should be top-dressed annually with decayed manure and given plenty of water in dry weather.

Helleborus niger is the best known species, and bears white flowers from December to March. H. juvernis has very fine white flowers, and blooms during the same period, but is not so hardy as the former.

The Lenten Rose is often confused with the Christmas Rose, but the flowering period of this plant is from January to April. There are several kinds including H. atrorubens, deep purple; H. caucasicus, pale green, and Duchess of Cleveland, rose-lilac. *W. Miller, Warley, Essex.*

THE MIXED FLOWER BORDER.

A charming flower border is one composed of the various sections of flowers—perennials, biennials, annuals, fibrous and bulbous. It may be of any size, long or short, narrow or wide, and according to these dimensions, furnished with suitable plants, a narrow border asking for plants of dwarfer habit than those of a wide border. Hollyhocks and other tall plants which add to the dignity and good effect of the latter are quite unsuitable for the other.

A vast amount of pleasure may be obtained from a border of this kind, if arranged so that a choice selection of spring-flowering plants commences the year, and is followed on until latest autumn, with the added pleasure of a changing group of colours, as for instance, of yellow, blue and red in spring, blue in the time of Delphiniums, yellow again later, and a change to shades of rose, mauve and white later still. There is, in fact, no end to the combinations that with forethought may be worked out.

But one must be careful in the choice of material, of which there is probably an over-abundance, and, moreover, in the case of choice annuals, one must be sure that the colours are true, which frequently means the saving of one's own seeds. The soil, too, needs attention, for unless it is kept quite fertile, not all the plants will come up to expectation. On that account I have for a long period lifted all but a few plants in the latest autumn, cultivated the ground, adding rotted dung, and re-planting the roots immediately behind the diggers. By this treatment, too, the arrangement may be altered every year, thus adding to the pleasure one expects: for change is always pleasing. Again, in April or early May a top-dressing of artificials or of pigeon

Digitized by Google

manure or soot is worth consideration. Trampling the border as soon as it is dry enough in spring is to be commended. The plants grow far better in firm than in loose soil, drought is less obvious in its effects, and, of course, a hoe must be run through the surface to at once render it smooth, and produce a loose buffer against the dry air.

Should a hedge of any kind form the back of the border, the roots must be cut close in every year at the annual digging, and the same with Box edging, if that material is employed.

I consider the main bulk of the plants should be herbaceous perennials, the positions occupied by spring-flowering bulbs being filled later with annuals, biennials and choice florists' flowers. The first essential of all sections used is, of course, pure and beautiful colouring, and while that is kept in view in the case of perennials, one may strain a point and find a place for interesting plants whose contribution to colour is nil. Examples of such are Eryngium pandanifolium, Euphorbia Lathyrus and Southernwood. They detract nothing from the general good effect, and they add considerably to its interest. On the contrary, there are some valuable plants such as Paeonies and Funkias that I would grow elsewhere, and Irises to some extent also, finding places however for Iris reticulata, I. sibirica alba and I. pallida dalmatica. Similarly with Phloxes, many of which, beautiful as they are, should be disposed by themselves, confining those for our border to a very select choice of which the old P. paniculata alba is by far the best. Naturally some of the colours detract from rather than enhance the beauty of the composition, and it may be stated that should this happen—and almost certainly it will—if any plant on flowering is discovered minimising the beauty of the border it should be removed and its place filled with a plant suitable to the position and its associates. *R. P. Brotherston.*

(To be continued.)

ALPINE GARDEN.

RANUNCULUS AMPLEXICAULIS.

THE Stem-clasping Crowfoot, Ranunculus amplexicaulis, is one of the best members of the family in every respect. It is so easily cultivated and so accommodating in the matter of soil and position that almost every flower lover who has a border or rockery can find a place where the plant will flourish and flower. It seems to prefer a rich, fairly stiff soil. In such a rooting medium it grows tall and strong, but in lighter and drier soil it will not live and flower so contentedly. It is a pretty, erect-growing plant varying from 6 to 12 inches in height, according to the nature of the soil and the amount of moisture present. It has somewhat narrow leaves which clasp the stems at their bases. The white flowers are of good size for the plant and of much beauty. They appear in spring and summer, and in favourable conditions the plant will last in bloom for some considerable time. In the Alpine garden this Crowfoot should be planted on a level spot not too high up the rockery. It is increased by division, and also by seeds when the latter can be procured, but these are slow in germinating. *S. Arnott.*

ERYTHRAEA MASSONII.

THIS is a most charming diminutive Alpine from the Azores. The plant revels in sandy soil, and produces a profusion of bright pink blossoms on slender stems not more than 4 inches high. Plants I saw at Southend-on-Sea this summer, although in full exposure to the sun, were well furnished with blossom. Partial shade is, however, beneficial to the plant, and it grows best in well-drained, sandy soil.

POTENTILLA AUREA.

POTENTILLA AUREA is a most beautiful and indispensable dwarf-growing Alpine for the rock garden. The close tufts of foliage are in summer freely studded with rich canary-yellow flowers that have an orange zone. It is a very effective Alpine. *W. L.*

TREES AND SHRUBS.

BRANCHES OF SHRUBS FOR DECORATIVE PURPOSES.

DURING recent years a good deal of attention has been paid to the production of long, slender growths of various trees and shrubs for room decoration, used either alone or with flowers. In some cases the branches are used in autumn for their coloured foliage, but in others they are cut indiscriminately, whether the leaves are green or coloured. For autumn effect the kinds with large leaves are most popular, but for general use small foliage and graceful habit are the points sought after.

To produce suitable branches it is necessary to cultivate plants solely for this purpose, the object being to obtain, long, elegant growths bearing healthy leaves and few or no side branches. To effect this the plants should be given rich soil and they must be cut down annually in the same way that Willow is cut down for basket-making. The plants are placed fairly closely together in nursery borders and are cut to within an inch or two of the ground line in February or March. Only those kinds that break freely after being cut down are worth using, and, as the method of cultivation is an exhaustive one, the plants should be fed liberally, and as soon as they show signs of exhaustion they should be replaced by young stock. Considerable numbers of shrubs and some trees lend themselves to this method of cultivation. Notable amongst shrubs there are Spiraea prunifolia flore pleno, S. arguta, S. Thunbergii, Tamarix pentandra, T. gallica, and T. tetranda, Prunus japonica flore pleno, Colutea arborescens, Cornus alba var. Spaethii, C. alba sibirica variegata, Prunus Pissardii, Stephanandra flexuosa, Acer palmatum and Kerria japonica. In addition, the evergreen Berberis Aquifolium is a very useful shrub for cutting during winter, for the leaves take on effective shades of red and bronze.

Amongst trees and shrubs with larger foliage than those already mentioned, there are Quercus coccinea, Q. rubra, Acer platanoides, A. Negundo vars. aurea and variegata, Sweet Chestnut, Liquidambar styraciflua, the Common Beech, and the purple-leaved Beech, Paulownia imperialis and Ailanthus glandulosa. The last two are not very useful for coloured foliage, but they form very large handsome leaves on stems six feet high, which are valuable where bold effects are desired in large rooms. The Paulownia has leaves two feet across and the Ailanthus produces foliage three feet long.

The same method of cultivation may be practised with certain kinds of shrubs in order that long, wand-like branches of flowers may, be cut in spring or early summer, for the plants may be forced or allowed to bloom naturally. For this purpose a few good plants are Prunus japonica var. flore pleno, Prunus triloba var. flore pleno, Spiraea arguta, Deutzia gracilis, Spiraea prunifolia flore pleno, Philadelphus Lemoinei and others of the same group, and Kerria japonica flore pleno.

Still another group of shrubs that may be grown on the same principal is that characterised by brightly coloured bark. Of these, Salix vitellina with yellow bark; the Cardinal Willow with red bark; Salix daphnoides with bluish or glaucous bark; Cornus alba and its varieties, with red bark; Leycesteria formosa, with green bark; the Philadelphuses, with brown bark, and Stephanandra flexuosa with brown bark, may all be easily grown and effectively used for room decoration in winter. These coloured-stemmed shrubs are not often seen in markets, although there is something to be said for their inclusion amongst the subjects used for room decoration.

Gardeners who are called upon to supply large quantities of flowers and foliage for indoor decoration, would do well to set aside a piece of ground for the cultivation of ornamental foliage that may be cut at any time without thought of whether a good plant is being injured or not. When branches are wanted and they are cut from ordinary shrubbery plants, not only is the future possibility of flowers impaired but the branches are less generally useful than are those that are grown specifically for the purpose in view. *D.*

ERINACEA PUNGENS.

The Hedgehog Broom, as this very dwarf shrub is called, is a native of Spain and although it has been known to our gardens for more than 150 years it is still rarely seen. For the rock-garden it is an ideal shrublet, for it seldom if ever, attains a height above 1 ft., but is usually only about half that stature. The almost leafless, grey-green branches, standing stiffly erect, are sharply pointed and when not in flower the shrub might easily be passed-by unnoticed. But in the later spring, when the sapless-looking twigs break into bloom, the little shrub becomes a most beautiful object. The flowers, borne in pairs or fours, are of the characteristic form of the Leguminosae to which E. pungens belongs. They are very large for the size of the plant (over half-an-inch long) and of a most charming soft blue colour, a tone which is rare in the Pea family.

E. pungens appears to be sufficiently hardy for most places, but it is an inveterate sun-lover and one that enjoys a warm nook with ample drainage. It occasionally sets seed in this country, but the usual method of propagation is by cuttings or layers,

SYRINGA VILLOSA.

Though long known in this country this Lilac, a native of Northern China, is still far from common in gardens, yet it is a shrub of undeniable merit. Whether grown as a specimen or associated with other shrubs of like character it is always a striking and interesting object.

S. villosa is a deciduous species, sending its erect, or slightly-arched branches to a height of some 10 feet. The olive-green leaves are narrow and pointed and about 2 inches long near the extremities, but when the shrub is planted in good soil those nearer the ground will be two or three times as long with a broad, rounded base, and tapering to a fine point. The blossoms appear in the late spring or early summer, when those of most other Lilacs are over. They break from terminal buds of the current year's shoots in a beautiful inflorescence, 6 inches to 12 inches long, and in colour are a bright rosy-lilac. There may be two or three of these handsome panicles drooping elegantly from the tips of the graceful branches and the flowers have a delicate and refined fragrance. S. villosa is quite hardy. It will succeed in an ordinary well-drained loam in an open situation. A top-dressing of half-decayed manure in early spring is of benefit to the plant. *A. T. J.*

CAMELLIAS IN THE OPEN.

Concerning Mr. Stenning's remarks on page 260 that it is only in the warmer parts of the country that Camellias do really well in the open, this is, no doubt, true, but it is also equally true that the Camellia is much hardier than is generally supposed. Where, however, there may be a doubt on the matter, the best way is to treat the Camellia as a wall shrub, tying in the growths to a wood trellis attached to the walls, or securing them with nails direct to the bricks, but not so tightly as to spoil the natural effect. Thus grown there are few gardens in which Camellias would not succeed successfully.

Another method of ensuring their well-doing in the open is to plant specimens between evergreen shrubs that are rather taller than the Camellias, thus forming a screen around the latter. Some years ago I saw this system adopted in a rather cold Middlesex garden, and it answered admirably, the flowers of the Camellia opening well. There were at one time splendid Camellias in the pleasure grounds of St. Leonard's Hill gardens, Windsor. *C. T., Ampthill*

THE IMPERIAL FORESTRY CONFERENCE OF 1923.

(*Continued from p.* 324.)

As a result of the hospitality extended to the Conference delegates by the Canadian Government and the untiring energies of the Forestry Branch, by whom the details of the programme were worked out, excellent opportunities were afforded of seeing all types of forest growth throughout the Dominion, varying from those in the Eastern provinces of Quebec and New Brunswick to British Columbia and Vancouver Island. In the course of these tours samples were seen both of forest types and also of lumber and pulp activities, which have done so much to change the character and value of the Canadian indigenous forest during the past fifty years.

To realise what these changes are a reference must be made to the original composition of the Eastern forests so far as tradition and the recollections of old settlers can go. Before the white man invaded Canada the whole of North Eastern America, extending from Labrador on the East to the Great Plains of Manitoba, was covered with a vast forest in which White Pine was the dominant tree wherever the soil was sufficiently deep and dry to maintain its growth. The Northern limit of this species appears to have been somewhere along the 50th degree of latitude, extending further north along river valleys, and ceasing in the south where the Laurentian Shield of pre-Cambrian rocks presented vast stretches of exposed rock and peat swamps on which White and Black Spruce, Jack Pine, Birch and Maple form the normal crop. The White Pine region appears to have embraced the St. Lawrence basin, the region of the Great Lakes, extended northwards wherever the soil and situation were suitable, and only stopped on the edge of the prairie where increasing aridity and the presence of alkaline soil checked further extension. To the South the barrier of White Pine extension was the Southern hardwood belt, which, increasing in vigour and complexity of composition, allowed the Pine to exist only where poor soil and exposed situations gave it the advantage over other species. Mixed with White Pine and forming a second story to it over vast areas were such species as Sugar Maple, Silver Maple, Paper Birch, Yellow Birch, Cypress, Hemlock, and many other subordinate species, above which the White Pine was able to stand out and develop unchecked by competition. Wherever soils were too thin or swampy White Spruce, Jack Pine, and Tamarack took its place, but scarcely a square mile could be found within its natural limit of distribution which did not show magnificent White Pines reaching to a height of from 150 to 200 feet and having diameters of from 4 feet to 6 feet at breast height. Plentiful proofs can be found to-day of the previous existence of these trees in the stumps and roots which occur everywhere on land cleared within the last twenty or thirty years, or which has been allowed to degenerate into scrub. Occasional patches of virgin White Pine forest still exist, but over the greater part of Eastern Canada this species only occurs in scattered clumps, and has almost passed out of commercial knowledge as a saw timber for export.

The forests seen to-day in Eastern Canada are almost entirely composed of species which the older lumbermen considered of no importance. Amongst Conifers White Spruce is probably the principal tree, with a certain proportion of Red Pine or Pinus resinosa, which by some freak of nomenclature is known as Norway Pine. Next in importance to White Spruce, Jack Pine is coming into prominence, while Cypress is also valued for shingles wherever it can be got in sufficient quantity. Mixed with these Conifers are the broad-leaved species already referred to, together with several Poplars such as Populus tremuloides, P. balsamifera, and P. grandidentata, while the Jack Pine is generally found in pure groups on the poorest soils, and Cypress and Tamarack in swamps or damp places. The Birches, Maples, and Poplars generally form a mixed forest with White or Red Spruce, the latter gradually getting the upper-hand if not interfered with by fire or cutting. The change brought about by the removal of White Pine has been entirely due to lumbering operations, and changes of a similar character are being brought about by the removal of the White Spruce, each species in turn being drawn upon to make good deficiences in the more valuable types.

Strange to say fire, which is responsible for so much of the devastation witnessed throughout the Dominion, is, under certain conditions and when confined to limited areas, one of the most valuable agents in bringing back both the Pine and the Spruce where these have been cut out in too reckless a manner in the past. By clearing the surface down to the natural soil, fire leaves a seed-bed on which Pine and Spruce are able to germinate and establish themselves better than where the seed falls beneath living trees, under which the shade is more or less detrimental to the young plants. If fires could be effectively controlled and lumbering operations restricted to reasonable limits, there is little doubt that Pine and Spruce would quickly restock the ground, but under present conditions not only are lumbering operations being carried on too rapidly to allow second growth to nature, but the appalling destruction caused by accidental fires during dry seasons periodically wipes out vast stretches of young middle-aged forest which should constitute future supplies.

After a forest fire the ground is thickly covered with stool shoots of Maple, Birch, Willow and Poplar, forming, in the course of a few years, a growth closely resembling pure coppice in many parts of England. An examination of the surface beneath this coppice usually reveals numerous seedlings of White Spruce and Jack Pine, and occasionally White and Red Pine, but owing to the dense canopy overhead these Conifers have little chance of working through to the light until the hardwood growth has opened out, either artificially or by the natural thinning which takes place by the suppression of the weaker branches. Provided seed trees exists in the neighbourhood, ultimate re-establishment of the Conifers appears to be the regular course of events, but when, as frequently happens, fires sweep over the area again and again, not only is the supply of seed gradually reduced, but the surface becomes sterilised by the destruction of humus, and more or less unsuitable for successful germination and establishment of delicate seedlings. Under these conditions Jack Pine appears to be the only tree which can hold its own, but even with this species the destruction of seed trees over wide areas must ultimately lead to its reduction and local extinction. Broad-leaved scrub appears to be the only type of growth which can renew itself more or less indefinitely, but as this is practically of no commercial value, the ground covered with it must be regarded as barren from an economic point of view.

How much of the surface of Eastern Canada has been reduced to the scrub stage by fire no one can say with certainty. Various estimates have been made, but all are more or less inaccurate owing to the impossibility of defining the boundaries of any particular class of forest on given areas. What may be regarded as scrub to-day may be a satisfactory forest of Conifers in fifteen or twenty years time These conversions from one type to another are continually going on. All that can be said with certainty is that scrub areas are increasing rapidly, and an estimate made by the Dominion Forest Service of 1,300,000 acres of young growth forest land burnt over annually may be rather below than above the mark.

Apart from the clearances made by lumbering and pulp-wood demands, and those caused by forest fires, the loss in the Eastern Canadian forest areas is determined chiefly by soil conditions. Where these are good, and the areas within easy reach of railway or existing settlements, clearances for agricultural purposes are being made at a fairly rapid rate, and naturally the best sites were given over to settlements so far back as 200 or 300 years ago, and these now form the chief industrial or trading centres of the Dominion. Land now being cleared for settlement is usually of a much inferior type to that cleared in the early days, and it is doubtful if many districts remain in the Eastern provinces which can be more profitably used for agriculture than for timber producing. This question has got to be taken up seriously in the near future. Hitherto the Government has been inclined to regard all settlements as beneficial, regardless of the fact that many abandoned farms and even villages can be found in every province, due to the fact that the soil conditions were hopeless for tillage purposes. So long as settlers can obtain employment in felling and sledging work during the winter they can generally exist with a minimum of land of an inferior type. When, however, this employment disappears through the working out of the surrounding forests, or the shutting down of saw or pulp mills, the settler is no longer able to sustain himself on the proceeds of his holding, and is usually compelled to leave the locality. The Forest Department is pressing strongly for a more accurate soil survey before settlements are sanctioned on Crown lands, and there is no doubt that this step will be taken in the near future.

The above facts are fairly generally recognised, not only by the Government and Forest Service, but also by lumbermen and pulp manufacturers, who realise that over-cutting and fire damage must be checked by some means or other if the forests of the Eastern provinces are to retain their productivity. Until quite recently it was generally supposed that pulp manufacturers had only to remove further north to obtain inexhaustible supplies of raw material. Recent surveys have shown, however, that although vast quantities of Spruce still exist in what is known as the "Northern Forest," yet these supplies are so scattered, and involve such a high expenditure in transport that it it doubtful if they can be made use of on anything like remunerative terms. Moreover, the fact has to be recognised that these remote forests are not only exposed to fire risk, but that the control measures which are possible in the neighbourhood of settlements or lumber mills are quite out of the question in remote regions. The regeneration of burnt forest of Black Spruce, the chief species in the North, is an extremely slow business, and probably little progress can be witnessed in less than a hundred years. Pulp mill proprietors are doing their best to check fires, and some have even instituted planting programmes, but the fact still remains that many of them are faced with a serious shortage within the next fifteen or twenty years, the alternative being either to draw supplies from distant fields, or to sacrifice vast capital expenditure by transferring their mills to other districts. *A. C. Forbes.*

(*To be continued.*)

THE FORESTRY COMMISSION.

At a meeting of the Forestry Commission held at Aberdeen this autumn, the Chairman, Lord Lovat, stated that the Forestry Commission proposed to carry out a scheme of planting 1,500,000 acres for the State, during the next eighty years, the most of it in the course of the next forty years. They also hoped to encourage proprietors not only to keep up their area, which was 300,000 acres before the war, but to convert the production from some twenty-seven cubic feet per acre to between fifty and seventy cubic feet. The Commission operating from London would control the questions of policy, finance, education, research and personnel. The executive work was delegated to assistant commissioners in England and Wales (one unit), Scotland (one unit), and Ireland (a third). On the educative and research side they hoped soon to formulate a policy for discussion with the various Universities and agricultural colleges.

VEGETABLES.

ONIONS FOR PICKLING.

Of all the uses to which Onions are put, pickling, until comparatively recent times, seems not to have occupied a very prominent place. Neither Miller in his famous *Dictionary*, 1759, nor Justice in the *Scots' Gardiners' Director*, 1754, have a word to say about their use for this purpose. Looking back over an experience of seventy years I note that the Onions used for picklers in my early days were the smallest bulbs taken from a general sowing of standard varieties.

Mr. Beckett, so recently as 1908, in his valuable book, *Vegetables for Home and Exhibition*, states:—"Pickling Onions may usually be selected in abundance from the general sowing of main crop and James's Keeping varieties, or a sowing may be made towards the end of April, thickly on poor soil." But later in the same work Mr. Beckett states:—"The variety named Silver Queen is very largely grown for pickling, and I know of nothing to equal it for the purpose."

Onions of the James's Keeping type have coloured flesh and are very solid, the flavour being more pungent than that of the softer, white-fleshed Onion. Where the eye has to be pleased, Silver Queen, pickled in white wine vinegar, is an easy first. Moreover, the larger varieties have thicker stems and this militates against the perfect sphere which is the ideal form aimed at; in addition to this there is a tendency to softness at the crown which is objectionable. To remedy this defect some growers chose the five-bladed variety, a small, globe-shaped, brown-skinned bulb with only two blades, each about the size of the leaves of Chives. John C. Circuit, market gardener at Rainham, Essex, grew a very large acreage of this Onion for many years, his manager, Henry Swann, having developed a special strain which yielded a very large percentage of "firsts" of a very pale colour when graded for bottling. After the bulbs had been ripened they were sent to East Ham to be skinned and brined, and for several months in the year travellers by rail to Southend had strong olfactory evidence of their whereabouts.

About 1867, Beck, Henderson and Child introduced a variety named Cantello's Prize, an extra early form of the pale sulphur-yellow strain of White Spanish. It was raised by a cloth weaver named Cantello. This variety soon became popular with the growers of pickling Onions, and is still highly esteemed for the purpose.

The Queen variety was sent out in 1868 by Waite, Burnell, Huggins and Co., and is still one of the most popular Onions grown. It succeeds in any climate, and is adapted to all the uses to which Onions can be put. If the spring-sown bulbs are lifted as soon as they are ripe and allowed to rest for a couple of months and then replanted, they produce in a very few weeks a shapely bulb from two to three inches in diameter, which, if properly cared for, will keep in sound condition until the following spring. In some of the warmer Colonies the bulbs are thinned and left in the ground until they have made this second growth. In more recent times extra early selections of the Queen, such as Barlatta and Marvel of Pompeii, have been raised, and these are equally valuable for pickling.

At the Wisley trials during the present year another silver white Onion made its appearance. The sample came from Morse of California, and the variety is named White Portugal. Although this variety has been known in America for many years, and is very largely grown there, especially in the South, little attention has been paid to it in Europe. It has a pure white, waxy skin and silver white flesh, and, as grown at Wisley this year, developed bulbs about the same size and shape as those of the Queen. The flesh, however, is more solid, and its keeping qualities are superior. It is quite distinct, and as it can be grown to a good marketable size, it is largely used for Onion sets. Like all other Onions of Southern origin, the flavour is pleasantly mild.

The name is unfortunate so far as Britain is concerned, seeing that the sulphur-coloured White Spanish has been known under the name of White Portugal for more than two hundred years. *S. B. Dicks.*

FRUIT GARDEN.

APPLE CUTTINGS.

May I remind your readers that they can now, when renovating old-established Apple orchards, utilise the sound branches cut off as Apple cuttings. The branches should be inserted about 3 feet deep in the ground, in open spaces between very old trees, in holes made by means of a crowbar. By this method, fruit-bearing trees are obtained much sooner than by re-grafting old trees. When the branch cuttings are fully established and growing well, the old and worn-out trees may be removed entirely. I am a visiting gardener in Somerset, and I am very sorry to see the Apple orchards in such a neglected condition, in striking contrast to those in Norfolk, where the soil is much poorer. *E. M. Hewat, Langford, Somerset.*

FIG. 123.—CHRYSANTHEMUMS IN THE CONSERVATORY AT HESKETH PARK, SOUTHPORT.

PUBLIC PARKS AND GARDENS.

CHRYSANTHEMUMS AT SOUTHPORT.

Southport must be included among the many towns in which there is a Chrysanthemum exhibition provided by the local authorities. Here, in the large conservatory at Hesketh Park, a very fine display has been provided and the skill with which the plants have been grown and arranged reflects the greatest possible credit upon Mr. W. Clark and his assistants. Plants carrying large flowers are grouped together in a huge bank, while on the side stages and the ground floor near-by many decorative varieties are displayed, including a number of varieties with single flowers.

Prominent amongst the large Japanese varieties to be seen at Hesketh Park are Edith Cavell, Frances Jolliffe, General Petain, Helena Margerison, Mrs. R. C. Pulling, Mrs. S. Chichester, the enormous Louisa Pockett, Major Chichester, Mrs. Algernon Davis, Mrs. J. Gibson, Fred. Green, Mrs. John Balmer, the highly coloured Lord Stuart of Wortley, Victory and Mrs. P. Murray. The illustration in Fig. 123 indicates the extent and beauty of the display in Southport's fine conservatory.

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

R. H. S. Award to the Grapes from Aldenham.—(See p 327).—I see in your issue of December 1 that my friend Mr. Dykes rebukes you for having "erroneously published a notice saying that a gold medal had been awarded to the grapes" recently exhibited by me. If instead of the word "awarded" you had written "unanimously recommended by the expert Committee appointed by the R.H.S. Council," you would have been strictly accurate. Two years ago I had the experience of having the unanimous recommendation of myself and colleagues ignored when we were acting as judges; now the unanimous recommendation of experts in my favour, when figuring as exhibitor, is similarly treated. As I do not propose to sell any medals that I may receive I am quite indifferent to what metal may be used in their construction, and am more than satisfied when experts decide that exhibits from the Aldenham garden are worthy of the highest honour. Nevertheless, proverbial wisdom has long ago decided that it is not a good plan to keep a dog and bark oneself, even though the R.H.S. Council may have formed a different opinion.—*Vicary Gibbs, Aldenham House, Elstree.*

—— As there has been some correspondence in your columns regarding the award made at the R.H.S. Meeting of Nov. 13 to the collection of Grapes from Aldenham, perhaps you will allow me, as Chairman of the Fruit Committee on that day, to state that the award recommended unanimously by the Fruit Committee was a Gold Medal, and that the Committee were not notified the Council had altered this award until a fortnight later. I understand that the exhibitor had first been notified of the Committee's recommendation of a Gold Medal, and afterwards that the award had been changed to a Silver-Gilt Medal. Some time ago the Fruit Committee made a protest to the Council concerning the alteration of its recommendations without first informing the members of such a decision, and the Council then arranged not to alter such recommendations without first interviewing the Chairman for the day. This arrangement was acted upon for a time, and I remember being sent for by the Council then sitting, to discuss with them an award of this kind; but the Council appears to have departed from that rule, and to have again reverted to the practice of altering awards without in any way consulting or informing the Fruit Committee of such a decision. Some of us feel that this is not quite a courteous way of treating a responsible Committee, whose members serve the Society to the best of their ability.—*Joseph Cheal.*

Castanea sativa heterophylla (see p. 309).—Some years ago Mr. W. J. Bean had a shoot of this variety of the Spanish Chestnut from Esher Common, Surrey, bearing leaves less than ¼-inch in diameter. This may have been the tree I noted on the same common about twenty years ago. In 1921, after the trees had been felled to a great extent, I found a young tree about six feet high, and this would seem to conform to the tree at Verrières, France, described by *A. M.* This young tree certainly bore dimorphic leaves, or they might be described as polymorphic, for scarcely two leaves are alike on a shoot I possess. Eight of the lower leaves are roughly linear, but vary in width in different parts, one having two finger-like lobes on one side. The five upper leaves are broad, but variously gashed or sinuate on one or both sides. The arrangement of the leaves all on one shoot is entirely different from those represented by Fig. 113, p. 309. Whether any of the forms is constant or not it would be difficult to say without seeing trees grown for comparison side by side for a considerable number of years. Certain it is that several names have been given to different forms, such as dissecta, dissecta nova, filipendula and linearifolia. A similar variation occurs in Fagus sylvatica heterophylla. *J. F.*

Sterility in Lilies.—With reference to the article on "Sterility in Lilies" (see p. 308), we have a considerable number of plants here, and although most of them were cut down after flowering, I know none of the Japanese Lilies would have developed seed pods. I did not see any signs of seeding on the Tiger Lilies, but one plant of Lilium regale carried three pods. I have sown the seeds from one pod out-of-doors and the seeds of another have been sown under glass. I shall be very much interested to see whether they produce plants. *F. L. Govett, Lavershot Homestead, Windlesham.*

Old Scottish Plant Names (see pp. 278, 312).—Cibes, Cives, or Civies for young Onions, are still current names in this district, as also is Bourtree for Elder; Tussilogie, Tushalogie, Dishalogie. for Coltsfoot, are also common. Is this a corruption of Tussilago? *J. G. Roberts, Trees Cottage, Barrhead, Glasgow.*

Eradication of Chickweed.—In reply to Mr. Brown's enquiry (see p. 282) as to the best method of eradicating Chickweed, I have found that pigs, old sows more especially, will pull up and eat every portion of the plant they can get at, and they do the work in a very short time, and also by treading on it, tend to solidify the ground, as Chickweed generally grows in very loose soil. *A. H. Maude, Finchampstead.*

Richardia africana Beyton Purity.—On the occasion of a recent visit to Mr. Jas. D. Hay, the well-known commercial fruit grower of Beyton, Bury St. Edmunds, I was shown several plants of a pure white Arum for which there ought to be a very large demand. The spathes are identical with those of the old favourite so far as size and substance are concerned, but they differ in being pure white and in having a much paler spadix. The plants have all the natural vigour of the type and cannot be distinguished from them except when in flower. Mr. Hay proposed to exhibit specimens before the Floral Committee of the Royal Horticultural Society and I shall be much interested to learn the opinion of that body. Its purity should ensure it a welcome for all the purposes to which the Arum Lily is put, and the fact that it is pure white will entitle it to a place in those floral decorations from which its parent is excluded owing to its colour. *H. J. W.* [So far as we are aware the R.H.S. Floral Committee passed this variety without comment on the 27th ult.—Eds.]

Loss of Scent in the Musk.—Apropos to this subject (see p. 273) it may be said that a botanical collector found it running wild or naturalised in the River Lyon, Glen Lyon, Perthshire, but it was quite scentless, and the reason presumed was that the proper insects for fertilising it probably did not exist in this country. During September last an announcement was made in a daily paper that the wild Musk of New Zealand, originally introduced by the settlers, was fragrant, and that the curator of the Royal Botanic Gardens had arranged for seeds to be sent to him. Some months ago the subject was discussed in the *Gardeners' Chronicle* (American), but no one in the United States seemed to possess the real old scented Musk. Last year some specimens were sent to England from New York, but they were scentless. The Musk is a native of North-west America, and surely it would not be impossible to find it there. If it is found to have lost its scent in its wild habitats, the fact would afford a fresh item for discussion in Hugo de Vries' theory of mutation in plants. Probably he would consider the scentless Musk only a variety and not an elementary species, because it has merely lost a character or quality in a negative way. *J. F.*

SOCIETIES.

DERBYSHIRE GARDENERS'.

THE show of the Derbyshire Gardeners' Association, held in the Royal Drill Hall, on November 9th and 10th, was considered to be the best Chrysanthemum show seen in Derby. Captain H. FitzHerbert Wright, J.P., performed the opening ceremony.

The entries constituted a record and the general effect and arrangement of the show earned many complimentary remarks. Foremost were the groups of miscellaneous plants, in and out of bloom, arranged for effect on a space of 144 square feet, in the centre of the hall. Mrs. WALTER EVANS, of Darley Abbey (gr. Mr. J. Maxfield), was placed first, a Gold Medal (offered by H. T. Ann, Esq., Derby) being included in the first prize, and it is interesting to note that this is the fourth successive year Mr. Maxfield has won this award. The group comprised a stately Kentia Palm at the head surrounded by winter-flowering Begonias, of the varieties Optima, Ideala, Exquisite, Scarlet Beauty, and Britannia, with Eulalias and Nandina domestica, while prominent at the corners were Cupressus macrocarpa lutea, intermixed with single and bush Chrysanthemums. Next in merit was a similar display by A. PRESTON JONES, Esq., Mickleover House (gr. Mr. J. Bacon), whose group contained Bamboos, Eulalias, splendid large Japanese Chrysanthemums, Primulas, Celosia pyramidalis, Dracaenas and exotic Ferns.

In the class for eighteen Japanese blooms arranged in six vases, J. G. Shields, Esq. offered a silver cup, which was won outright by J. A AITON, Esq., Duffield (gr. Mr. G. Neale); Mr. AITON was also awarded a special prize offered for the premier bloom in the Show, for the variety Majestic; second, G. H. STRUTT, Esq., Belper (gr. Mr. J. Tannock). Of seven competitors in the class for three vases of Japanese Chrysanthemums Mrs. WALTER EVANS was first and A. PRESTON JONES, Esq., second. The best table of large single Chrysanthemums comprising twelve vases in not fewer than eight varieties, arranged for effect to show one front, was exhibited by J. A. AITON, Esq.; second, Mr. J. BROWN, Kilburn.

For six vases of Perpetual Carnations, not fewer than three varieties, the first prize was won by Mrs. W. EVANS, and the second by LORD BELPER, Kingston Hall (gr. Mr. J. McCartency).

Six vases of two varieties of Violets were shown best by Mrs. W. EVANS: second, Mr. J. COLEY, Duffield.

In the Derbyshire Members' Classes a silver Challenge Cup, given by Messrs J. Peed & Son, West Norwood, for twenty-four single Chrysanthemums and twelve Japanese blooms, arranged for effect, was awarded to Mr G. H. STRUTT; second, LORD BELPER.

For eighteen Japanese blooms, Mr. G. POTTER Derby, was first, and for twelve incurved blooms, Mr. G. H. STRUTT excelled. The best group of Chrysanthemums in a semi-circle occupying thirty square feet was shown by Mr. A. SCAIFE, Risley, the award including a special prize offered by Mr. J. M. Stewart, seedsman, Derby; second, Mr. G. POTTER, Derby.

Other prize-winners were:—(a) Six table Plants; first, Mr. G. H. STRUTT; second, Mrs. W. EVANS. (b) Six winter-flowering Begoinas in variety; first, Mr. J. A. AITON; second, Mrs. W. EVANS. (c) Six Salvias; first, Mr. J. A. AITON; second, Mrs. W. EVANS.

In the open classes for fruit the quality was excellent

For Apples and Pears, Mrs. W. EVANS was first and Mr. J SNAIPE second. The Silver Challenge Cup offered by F. N. Smith, Esq., Wingfield Park, for a collection of fruit, with decoration, was won by Mrs. W. EVANS; second, LORD BELPER, who exhibited excellent bunches of Black Alicante Grapes.

In the class for two bunches of Black Grapes, LORD BELPER was first with Ali-

Digitized by Google

cante; second, Mrs. W. EVANS; and this lady was first for two bunches of White Grapes, showing Muscat of Alexandria very well finished.

In the Open Vegetable Class for nine kinds, the first prize was awarded to Col. SCOTT, Draycott (gr. Mr. J. Woodward).

READING AND DISTRICT GARDENERS'

THE meeting of this Association, held on Monday, 19th November, was set apart as an "Open Meeting," when lady friends are invited. The President (Mr. Councillor Frank E. Moring, presided, and among the large audience present were Mr. Leonard Sutton (Vice-President), Mr. Martin H. F. Sutton, Mr. E. P. Foquett Sutton, Mr. L. H. Sutton, Mr. Councillor T. Waldron (Honorary Members), Mr. A. H. Fulker (Chairman), and Mr. M. Goddard (Vice-Chairman). The subject of the illustrated lecture given by Mr. F. Townsend, Hillside Gardens, Reading, was "A ramble among the flowers in a Berkshire garden," and by the aid of a beautiful series of auto-chrome slides, he was able, in imagination, to conduct the party through the glasshouses at Hillside from the first of January to December 31st. Commencing in the spring, groups and specimen plants of Cinerarias, Tulips, Daffodils, Calceolarias and annuals in pots under glass came under notice. Then followed spring bedding plants, including lovely views of Daffodils in the grass. Summer greenhouse flowers were represented by Gloxinias, Streptocarpus, &c.; summer bedding by Antirrhinums in beds and borders, Salpiglossis, Asters, Stocks, in fact by all the leading sorts of half-hardy and hardy annuals. Autumn time brought pictures of Begonias, Primula obconica and Chrysanthemums, and winter, those most popular of Winter-flowering plants, Primulas and Cyclamens.

In the competition for six Onions there were eight entries and the first prize was awarded to massive bulbs of Ailsa Craig shown by Mr. D. TURNER, Coley Park Gardens.

In the non-competitive section a First Class Certificate was awarded to Mr. E. BLACKWELL (gr. to Mr. H. Hirst, Foxhill, Reading), for massive blooms of Mrs. R. C. Pulling Chrysanthemum, whilst a similar award was given to Mr. R. BULLER, a Reading allotment holder, for fine bulbs of Al and Ailsa Craig Onions. Award of Merits were made to the following: Mr. A. H. FULKER, Elmhurst Gardens, Reading, for decorative Chrysanthemums; Mr. G. TOVEY, Leighton Park Gardens, Reading, for decorative Chrysanthemums, and Mr. H. SHARPE, Tidmouth Grange Gardens, Reading, for single Chrysanthemums.

Five new members were elected.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

Thursday, November 8. *Committee present*: The Rev. J. Crombleholme in the chair). Messrs. R. Ashworth, J. Birchenall, A. Coningsby, D. A. Cowan, J. Cypher, J. Howes, J. Jackson, D. McLeod, E. W. Thompson and H. Arthur (Secretary).

FIRST CLASS CERTIFICATES.

Brasso-Laelio-Cattleya maculata magnifica (*B.-L.-C. The Baroness* × *L. C. Thyone*). A well-formed flower with canary-yellow coloured petals, the sepals and lip being a richer shade of yellow. The lip is frilled and margined with rose. From S. GRATRIX.

Odontonia Papillon (*M Bleucana* × *Odm. loochristiense*) a very fine hybrid, the flowers heavily spotted with reddish-brown on a rich yellow ground. From P. SMITH, Esq.

AWARDS OF MERIT.

Odontoglossum Mrs. James Wood; *O. crispum Rosy Rapture*; *O. promerens, var. Sunbeam*; *Cypripedium Bright Eyes* (*Earl Tankerville* × *Sultan*); *C. Madrigal* (*Charltonii* × *Royal George*); and *Laelio-Cattleya Eastern Monarch.* (*L.-C. calistoglossa* × *Mendelii*). From S. GRATRIX, Esq.

Cypripedium J. M. Black, West Point var; *C. Papyrus* (*Earl Tankerville* × *Charlesworthii*) and *Laelio-Cattleya Glory, var. Golden King* (*C. fulvescens* × *L.-C. Thyone*). From MRS. GRATRIX.

GROUPS.

S. GRATRIX, Esq., West Point (gr. Mr. J. Howes) was awarded a Silver-gilt Medal for a group.

Messrs. J. Cypher and Sons, Cheltenham, staged a group for which a large Silver Medal was awarded.

Thursday, November 22.—Committe present: R. Ashworth, Esq. (in the chair), Messrs. A. Coningsby, D. A. Cowan, J. Cypher, A. G. Ellwood, J. Evans, J. Howes, J. Jackson, A. Keeling, D. Losh-Thorpe, E W. Thompson, and H. Arthur (Secretary).

FIRST CLASS CERTIFICATE.

Cypripedium Maudiae, Westonbirt var., the finest variety of the type. From Messrs. KEELING AND SON.

AWARDS OF MERIT.

Cypripedium Major Keppel and *C. Mrs. Keppel* (both of unknown parentage). From the Hon. ROBERT JAMES.

Odontoglossum promerens rotundum. From P. SMITH, Esq.

Cypripedium Mrs. James Wood (parentage unknown). From JAMES WOOD, Esq.

GROUP.

Messrs. CYPHER AND SONS, Cheltenham, staged a group for which a Large Silver Medal was awarded.

NATIONAL CHRYSANTHEMUM.

THE output of new Chrysanthemums has been well sustained throughout the present season, for even so late as November 26 no fewer than twenty varieties were submitted for the consideration of the N.C.S. Floral Committee at Westminster, notwithstanding the cold and very foggy weather prevailing. Awards were made as follow:—

FIRST-CLASS CERTIFICATES.

Mrs. Arthur Brown, II.i.a.—This is a large, full, Japanese variety of great substance; the colour is pale blush. Shown by Messrs. KEITH LUXFORD AND CO.

Monarch, II.2.a.—A big incurving Japanese variety with very broad florets; the colour is bronze-buff, a pleasing and effective shade. Shown by Mr. H. SHOESMITH.

Chestnut Glory. V.2.a. — A bright and pleasing single variety of medium size. The colour was officially given as terra-cotta bronze, a description which suggests the difficulty of defining the shades of colouring in many new varieties. Shown by Mr. G. CARPENTER, West Hall Gardens, Byfleet.

Lynette. II.1.b.—One of the most beautiful white varieties we have seen for a long time. The flowers are of medium size and Japanese form, but the florets reflex regularly and gracefully, making up bloom of great refinement and one that will last a long time when cut. Shown by Messrs. CRAGG, HARRISON AND CRAGG.

Mrs. Charles Fox. II.2.a.—A yellow Japanese variety of good size, with loosely incurving florets of clear golden yellow colour. Shown by Mr. C. FOX, Linden Gardens, Tunbridge Wells.

W. H. Bilney. II.1.a.—An immense Japanese variety of full exhibition size and yet quite graceful and attractive by reason of its long gracefully drooping florets. The latter are rich golden yellow but the outer florets are shaded with crimson. This fine variety was inadvertantly placed before the Committee under the name of Mrs. Gertie Salmon. Shown by Mr. T. STEVENSON, Cowley.

Star of Gold. II.1.c.—A useful decorative variety with short slightly reflexing florets; golden yellow; stems long and stiff. Shown by Mr. T. STEVENSON, Cowley.

COMMENDATION.

Dainty. II. 1. c.—A pleasing decorative variety of the smaller Japanese type, but, nevertheless, very pretty, and well named, as the colour is shell pink. Shown by Mr. H. W. THORPE, Worthing.

Obituary.

T. F, Cheeseman. We have received news of the death of Mr. T. F Cheeseman, botanist, and curator of the Auckland Museum, at Auckland, New Zealand, on October 15th. Mr. Cheeseman was born in 1846 at Hull, Yorkshire, arriving in New Zealand, with his parents, at the age of eight years. Botanists will know him through his *Manual of the New Zealand Flora*, which deals with a subject he had continuously studied since 1876, and during the intervening years he had visited all parts of New Zealand from the North Cape to Otago, and also the Kermadec Islands, a group lying 600 miles north of New Zealand. He had recently completed fifty years service as Curator of the Auckland Museum, which he had brought into the front rank of similar institutions. It is a matter for regret that he could not have lived to see the splendid new building about to be erected as a War Memorial—chiefly at his suggestion. As recently noted, a new edition of his *Manual* is in the press, the first edition published in 1906 having run out of print. A companion work is Mr. Cheeseman's *Illustrations of the New Zealand Flora*, in two large volumes, which was published in 1914. Mr. Cheeseman was awarded the Hector Memorial Medal in 1918 by the New Zealand Institute, and this year the Linnean Society awarded him its medal. New Zealand with the unique and varied flora has attracted many noted botanists and among the names of those noted men from Banks and Solander in 1769 to the present day that of Thomas Frederick Cheeseman will not be counted the east.

TRADE NOTES.

MR. R. S. STURTIVANT, Secretary of the American Iris Society, in an article in *The Flower Grower*, U.S.A., passes a great compliment to raisers of Irises in this country and especially to the work done by Mr. Amos Perry. He states: "The Perry Catalogue is, I think, the outstanding one this year. There are a host of new varieties, some of which were registered recently, and the descriptions just bristle with fascinating terms like apricot, rose, and crimson. Report has it that many of these new seedlings were derived from an extremely tall seedling of no intrinsic merit except height, and that they carry this good quality. For the most part they seem to be pallidas and neglectas, often with velvety falls."

MESSRS. KENT AND BRYDON, Darlington, send us the following comment on the crop of Potato Catriona grown by Mr. H. S. Dean, Elton Hall Gardens, Peterborough, referred to on p. 312:—"It may interest your readers to know that Mr. Dean was awarded 1st prize for the best dish of this variety at the National Potato exhibition at Birmingham, where our stocks gained 1st, 2nd, 3rd and 4th prizes in this class. The prize of £5 was offered for the best six tubers, open to all."

GARDENING APPOINTMENTS.

Mr. G. Humphrey, previously Gardener at Wooderoft, Rochester; Coldharbour Park, Hildenborough; Kingsmead, Matfield, and Ewell Manor, West Farleigh, as Gardener to Colonel Bartley, Brandfold, Goudhurst, Kent. (Thanks for 2s. 6d. for R.G.O.F. Box.—EDS.).

Mr. C. Frost, for the past five years Gardener to Col. C. W. DARWIN, C.B., at Elston Hall, Newark, Nottinghamshire, as Gardener to Sir ROBERT KINDERSLEY, Plaw Hatch Hall, Sharpethorn, Sussex,

Mr. F. H. Stenner, for four-and-a-half years Gardener to C. H. WILDING, Esq., Wexham Place, Stoke Poges, Buckinghamshire, as Gardener to M. U. DEWAR, Esq., Danesbury House, Welwyn, Hertfordshire.

Mr. F. J .Stapley, as Gardener to T. P. TEW, Esq., Brightling Park, Brightling, in succession to the late JAMES STAPLEY. (Thanks for 2s. 6d for R.G.O.F. Box—EDS.)

Mr. Frankish, for over eight years Gardener to Major W. EATON WALKER, V.D., as Gardener to Sir DENNIS READETT BAYLEY, K.B.E., Staunton Hall, Nottinghamshire.

Digitized by Google

ANSWERS TO CORRESPONDENTS.

CELERY WILH PITHY STALKS: *E. B.* The pithy nature of your Celery is caused through drought at the roots followed by copious watering. An excess of nitrogenous manure at the roots and earthing up the plants too soon will also cause the stems to become pithy.

EMBOTHRIUM AND PERSIMMON: *J. O. M.* Write to Mr. G. Reuthe, Nurseryman, Keston, Kent.

EMPLOYER'S LICENCE FOR GARDENER: *H. P.* It is clear from the Regulations that an employer must take out a licence to employ an under-gardener under the conditions named by you. It would be otherwise if the man were employed merely occasionally or in the capacity of a labourer.

FAILURE WITH GRAPE VINES: *W. S. C.* As your vines used to crop well we can only suggest that their failure in recent years is due to neglect during the war period. Dress the rods with Gishurst Compound, thoroughly cleanse all parts of the vinery with soft soap and sulphur and wash the walls with hot lime wash and sulphur. Afterwards lightly point the surface of the border, remove all loose and inert soil and provide a top dressing of some approved vine manure added to fresh loam and lime rubble. Pay careful attention to watering and to ventilating, and be particularly careful to provide sufficient atmospheric moisture during hot weather. Train the rods at least twenty inches below the glass. Crop the vines lightly next season, and in other ways encourage them to make as much healthy growth as possible; if they fail to respond to this treatment, they should be rooted out and the vinery replanted next season

FUNGUS ON BRASSICAS: *A. E. J.* The fungus attacking your Brassicas is Cystopus candidus, or White Rust. This disease frequently develops extensively on species of Brassicas during damp, mild weather, Nothing can be done to exterminate the fungus once it has attacked the plants, but its presence may be reduced by the avoidance of close planting and over manuring.

GOOSEBERRY SHOOTS: *H. F.* The shoots are not affected by Gooseberry mildew; the symptoms are those of attack by aphis, which was doubtless present on the bushes earlier in the season.

NAMES OF PLANTS: *Reader.* 1, Fuchsia Thalia (hybrid); 2, Pilea spruceana; 3, Fuchsia splendens; 4, Hymenanthera crassifolia; 5, Epilobium nummularifolium; 6, Thymus Serpyllum.—*G. R.* 1, Taxodium. distichum (Deciduous Cypress); 2, Quercus acuta, var. ambusaefolia.

POTATOS WITH SCABBY SKINS: *J. H.* The tubers are affected with Potato Scab, Actinomyces scabies. The presence of scab may almost certainly be attributed to your use of sea-sand; sea-weed would not cause it. Your best plan is to dig or plough into the soil a green manure or a green crop. In gardens and small holdings decayed leaves, spent Hops, and grass mowings may be incorporated with the soil. Where grass mowings are plentiful these certainly should be used, as they give excellent results. The materials mentioned should be dug in the soil previous to planting the tubers, at the rate of a barrow-load to four square yards. The grass may also be placed in the trenches at the time when the tubers are planted, but in this case care must be taken not to place the grass too thickly about the sets or the latter might be injured through the grass fermenting.

Solanums, per doz.	12 0	–15 0

REMARKS. — Supplies were held up during most part of last week owing to the severe weather. Ericas are the main attraction in flowering plants. Chrysanthemums begin to show signs of finishing. Solanums are in first-class condition and the demand is fairly good. Ferns and Palms of various sizes, of the usual market sorts, appear to be fairly plentiful. Business should be more brisk in this department during the next fortnight, to meet the requirements of the provinces. A few Azaleas are now on sale, principally coloured sorts.

REMARKS. — There has been a general falling off in supplies during the past week, especially amongst Carnations and Roses. Carnations advanced to 6s. per dozen for best bloom on Thursday and Friday of last week, and all supplies were cleared very early. The principal varieties offered are Aviator (scarlet), Carola and Enid (crimson), Delight, Enchantress Supreme, Laddie, May Day, Mrs. Hemus, Mrs. Ward, Peerless, Winsor, Daydream (pink), White Wonder, White Enchantress, and White May Day. All these are arriving in good condition and supplies are a little more plentiful this morning. Roses are also fewer, and prices firmer. There will be practically no supply of Lily-of-the-Valley from home growers for a few days; only small consignments from Holland are available. Roman Hyacinths are arriving in larger quantities. Chrysanthemums are chiefly of the varieties mentioned last week, but all are a little firmer in price. Liliums remain as quoted previously. Richardias (Arum) are more limited, and their prices are rising. English Violets are exceptionally scarce, owing to the severe weather.

REMARKS.—In more than one section there is a tendency for business to improve which, after the dull period of the last week or two, is a satisfactory change. Canadian and American Apples are quoted comparatively low and ample stocks are in the country. English Apples are scarce; first grade cookers are keenly inquired for. Cox's Orange Pippin is also in demand. A better trade is being experienced for hothouse Grapes and both home-grown and Belgian produce is selling freely. A fair demand is ruling for South African and Jamaican Oranges. Oranges from Spain are plentiful and moving slowly. Tomatos from the Canary Islands are not selling so freely as could be desired, and prices will probably weaken in this section. English Tomatos are almost finished; the bulk of recent consignments have not realised prices sufficiently high to cover expenses, and only well coloured fruits of the new crop are wanted. A few Cucumbers are selling fairly well but supplies are small. English Asparagus is selling badly, well coloured Paris Green Asparagus being a serious competitor with the home-grown heads. After a quiet time there is an improvement in the demand for Guernsey Beans, and their prices are now at a better level from the producer's point of view. Beans from Madeira this week were in fair condition and sold moderately well. There is little or no improvement in the trade for new Potatos. Small quantities of Seakale are on offer at a firm price. Brussels Sprouts and Cauliflowers are fairly plentiful and selling well. Mushrooms are a steady trade and prices remain firm.

Rothamsted and Agricultural Science.

THE achievements of the Rothamsted Experimental Station have often been recounted, but we doubt whether they have ever been presented with such clarity and succinctness as they are in Sir John Russell's address.* These achievements are being steadily augmented year by year, and as knowledge of the growth of crops becomes more precise, it becomes necessarily of more value to the gardener. In the old days, when experience of the value of artificial fertilisers was but fragmentary, the scientific and economic use of fertilisers as means of supplementing farmyard manure, seemed easy of realisation. Once gardeners had grasped the elementary facts that most soils benefit by the application of lime and most crops give larger yields when supplied with fertilisers containing nitrogen, phosphorus, and potash, it seemed as though all that need be known was known. But, as more and more experiments were made, it was discovered that these three types of artificial manure have each their special role to play. Thus it was found that nitrogen-containing manures are specially effective in promoting leaf growth and phosphatic manures in augmenting root—and fruit—growth, whilst potassium-containing manures are particularly potent in promoting the growth of "roots"—Turnips, Swedes, Potatos and the like. Hence there grew up the practice of using special manures—nitrogenous, phosphatic, or potassic—for different crops. With further investigation, however, the discovery was made that as circumstances alter cases, so seasons and soils affect the value of fertilisers. For example, as Sir John Russell points out, the long-continued experiments on the heavy land at Rothamsted show clearly that in some seasons complete artificials give better results than are obtained by farmyard manure (at the rate of fourteen tons to the acre), and that in other seasons the farmyard manure plots give a higher yield than is given by the complete fertiliser plots. This fact, although of general interest, is of no particular practical significance to the good gardener who applies to his crops not only farmyard manure but artificial manures, *e.g.*, phosphatic and potassic fertilisers, as well. There are, however, other facts of the same order related by Sir John Russell, which are of great practical value to the gardener. Thus a complete artificial manure which proved to give excellent results on the Rothamsted soil was found, when applied to the light sandy soil of Suffolk, to increase the yield of Barley by only five-and-a-half bushels per acre. When, however, phosphates were *omitted* from the fertiliser, the yield was increased over that obtained with the use of the complete fertiliser by no less than six bushels. The explanation of this curious fact is simple. Light soils are early soils. In a dry or even normal year the crops upon them will finish early—it may be too early indeed for a full yield. By adding phosphates the earliness is yet further promoted, and hence the smaller yield obtained by the use of the complete fertiliser. Evidently this property of phosphatic manures must be taken into account by the gardener and exploited by him. If he wants earliness and is not so set on yield, he will be helped to achieve his object by making use of phosphatic manures even though his soil be light. If the soil be heavy, he can hope for larger and less belated crops by employing phosphatic fertilisers. Recognising that the effect of manures varies with many factors, Rothamsted has set itself the laborious but highly important task of disentangling those factors and estimating their several results. Already conclusions of importance have been reached. It has been shown, for example, that yields from plots manured with farmyard dung fluctuate less than those from plots on which complete artificials are used. It has also been shown that in a year following an autumn rainfall above the average, manures generally give results above the normal; but if more than an average amount of rain falls in summer, manures fail, as it were, to pull their weight and the crops treated with them are smaller than might have been expected from experience of average years. Spring excess of rain appears to interfere less with the beneficial action of manures. Sir John Russell hopes that presently weather effects and soil-condition effects on yields will be known with such certainty that experts may be able to give an accurate forecast to farmers of the likelihood of the application of a prescribed artificial fertiliser increasing a given crop by a definite amount. He points out that were this to become possible a farmer would be able to insure his growing crop. Gardeners will be also deeply interested to learn that the Rothamsted experiments justify their determined preference for farmyard manure; although it scarcely needs to be repeated that this preference, if it excludes the supplementary use of artificials, is mistaken and uneconomical, and is becoming more and more so every day. But as between a complete artificial and farmyard manure, Rothamsted finds that the latter is rather more efficient than the former and, what is even more important, that the farmyard manure maintains the fertility of the soil better than does a complete artificial fertiliser. This conclusion is of special interest, for it proves that the opinion held by Lawes and Gilbert that farmyard manure owes its fertilising value solely to its ash and nitrogen compounds is, though mainly, not wholly accurate. What is this extra virtue possessed by farmyard manure? This problem is now engaging the attention of the investigators at Rothamsted. The general opinion, of course, is that farmyard manure affects favourably the porosity of the soil—increasing pore space and thereby providing for a larger reserve of water and a better supply of air in the soil. But it is possible that other effects co-operate with these. In its gradual decay, farmyard manure gives rise to a series of compounds, and some of the intermediate members of this series may be of special value as plant food. Lastly, no account, however brief, of the work of Rothamsted may omit mention of the discoveries concerning the microflora and fauna of the soil. These discoveries reveal the soil as the natural home of numerous micro-organisms, the members of each of which are constantly increasing or decreasing. Every day throughout the year the total and relative numbers of the soil population change, and it is significant that increase of soil-amoebae—which prey on bacteria—is attended by decrease of the latter and decrease of the amoebae by increase of soil-bacteria. No one can peruse Sir John Russell's account of the work of the Station over which he presides with such energy and distinction, without expressing gratitude for and pride in the work which is being done at Rothamsted, nor without a recognition that the method of work practised there must have no less in the future than it has in the past great and beneficial influence on the progress of the science and practice of agriculture and horticulture.

* A Discourse delivered at the Royal Institution, February, 1923, by Sir E. John Russell, F.R.S.

"Gardener's Chronicle" Almanac for 1924.—We shall publish in our issue of January 12 a "Gardeners' Chronicle" Almanac for the year 1924. In order to make it as useful as possible for reference we shall be obliged if Secretaries of Horticultural, Botanical, and Allied Societies, or any of our correspondents WILL SEND US IMMEDIATE INFORMATION OF ALL FIXTURES FOR THE ENSUING YEAR.

Flowering Plants of South Africa.—Part 12 of Volume III. of the *Flowering Plants of South Africa* contains illustrations and descriptions of ten plants. Aloe microcantha (tab. 111), has the characteristic concave leaves with rigidly ciliated margins; from the crown of leaves arises a tall corymbose inflorescence of tubular flowers that are pale red at the base tipped with green. The plant flowers during January and February and so soon as the seeds have set, a few months later, the leaves wither almost completely to their bases. The plant was figured in the *Botanical Magazine* so

Digitized by Google

far back as 1821. Erythrina Humeana (tab. 112), is a very bright Leguminous plant with a spike of dark red flowers that are succeeded by articulated pods of a violet colour. This species was also figured many years ago in the *Bot. Mag.*; it has been in cultivation in Europe for over one hundred years. Adenia digitata (tab. 113) is a member of the Passifloraceae, and both the roots and fruits are poisonous. It has long, graceful branches provided with tendrils by which it climbs up neighbouring bushes and shrubs. The flowers are axillary and not so attractive as in most of the Passiflora race. Wachendorfia paniculata, (tab. 114) is said to have been noticed in the Kew Gardens so far back as 1867, but it is not of very great value in gardens. The inflorescence has a somewhat superficial resemblance to that of Tritonia; the petals are dull yellow with bronzy-red markings and the flower buds are also bronzy-red. Crassula congesta (tab. 115) was first described by Mr. N. E. Brown in *Gard. Chron.*, September 6, 1902, p. 171, who stated that it was of botanical rather than of horticultural interest. Gladiolus psittacinus (tab. 116), is the showiest of the ten plants illustrated in Part 12 and well-known in gardens in this country. It is figured in the *Botanical Magazine* (tab. 3032) and was known in cultivation in England as early as 1830. Venidium macrocephalum (tab. 117) in an interesting Composite that is said to be well worth cultivating for supplying cut blooms, as the plant flowers freely and makes a splendid display. The flowers are about two inches across and have pale yellow florets. The ray-florets are lemon-chrome with orange at the base; the cushion-like disc is brownish-red. Lonchostoma monostylis (tab. 118) is a member of a genus comprising only four known species. It is said to be a graceful plant with long, thick, erect stems, at the apices of which the flowers are borne in heads. Eulophia Zeyheri (tab. 119), is an Orchid sometimes known as Eulophia bicolor and was successfully cultivated by the late Mr. H. J. Elwes. It is figured in the *Bot. Mag.* (tab. 7330) but the colouring on the lip is quite different in the two plates, being more purplish violet in the one under notice and the petals and sepals yellow. Hessea Rehmanni (tab. 120) is an Amaryllidaceous plant with flowers that suggest a Crinum. The plant usually produces only one leaf which is either quite terete or has a shallow channel. The peduncle is also terete and is terminated by an umbel of about nine flowers, the segments of which have wavy margins.

R.H.S. Rose Judging Committee.—The Council of the Royal Horticultural Society has invited the following to form a Judging Committee for their trials at Wesley of Roses for garden purposes, and all have accepted the invitation. Chairman, the President of the R.H.S., the Rt. Hon. Lord Lambourne, J.P., V.M.H.; the Chairman of the Wisley Committee, Mr. W. Cuthbertson, J.P., V.M.H.; Mrs. Wightman, of Bengeo; Messrs. Wettern, Holland, Darlington; Drs. Lamplough and Williams, Messrs. Easlea, Prince, G. M. Taylor, A. Dickson, jun., Hay, Coutts, Pernet Ducher, and Poulsen.

National Hardy Plant Society.—The second issue of the *Journal* of the National Hardy Plant Society is a great improvement on the first. The reading matter and illustrations extend to fifty-two pages, and the principal contents are "The Bearded Irises," by Mr. A. J. Bliss; "Methods of Propagation," by Mr. R. V. Giffard Woolly, the Editor, which contains a list of months wherein seeds of certain kinds of plants should be sown; "British Plants in the Rock Garden," by Mr. Frank Bouskell, President of the Society; "New or otherwise Noteworthy Hardy Plants of 1921 and 1922"; and "About Staking Perennials." The *Journal* is well printed, amply illustrated, and a very useful publication. It is issued free to members of the Society and at 2s. 6d. to non-members. All communications concerning the Society and its *Journal* should be sent to the Hon. Secretary, 20, Tavistock Street, W.C.2.

Mr. A. MacKellar, V.M.H.—The King's gardener necessarily occupies an exalted position in ths world of horticulture, but among those who have had charge of the Royal Gardens at Windsor none has been more successful or more modest than Mr. A. MacKellar. He commenced his gardening career under his father at Auchindarroch House gardens, Argyllshire, and, as was the custom in those days, he was apprenticed to the profession of gardening. After his apprenticeship he served as journeyman under Mr. Niven of Hopetoun House, and thence went as outdoor foreman at Tyninghame House gardens under Mr. Lees. His next appointment was as journeyman at the famous gardens at Chatsworth under Mr. Speed. Later Mr MacKellar acted as general foreman at Penrhyn Castle and remained in these splendidly kept gardens for seven years. He left Penrhyn Castle to become gardener at Floors Castle, a position he occupied with great success—and wherein he became famous—for about ten years, when he obtained the appointment of gardener to King Edward VII. (then Prince of Wales) at Sandringham. After the death of Queen Victoria and soon after King Edward ascended the throne, Mr.

MR. A. MACKELLAR, V.M.H.

MacKellar left Sandringham to take charge of the gardens at Windsor and Frogmore, and this high position he has occupied to the utmost satisfaction of his Royal employers down to the present time. Mr. MacKellar's duties are onerous and extensive, and few people have any idea of the vast amount of produce he cultivates in the gardens and glasshouses at Frogmore, though some have a fair idea of his ability as a landscape and garden artist from their knowledge of the gardens around Windsor Castle and elsewhere. Both at Floors Castle and at Sandringham, Mr. MacKellar carried out extensive improvements, and at Frogmore he has reconstructed all the glasshouses and extended the fruit and kitchen gardens. Mr. MacKellar does not appear very prominently before the public, as his time is fully occupied in the conduct of the King's garden. He is, however, known to a wide circle of gardening friends and his skill as a gardener has won for him the award of the Victoria Medal of Honour in Horticulture from the Royal Horticultural Society. He takes a keen interest in the horticultural charities and endeavours by every means in his power to advance the education of young men who come under his charge at Windsor.

Bayley Balfour Memorial Garden.—We are asked to state that enquiries regarding the Memorial to Sir I. Bayley Balfour—of which full particulars were printed on pages 336 and 337 of our issue of December 8—and donations thereto should be addressed to Mr. John Sutherland, 25 Drumsheugh Gardens, Edinburgh. Donations to the Memorial Fund and promises of financial support amounting to £600 have reached the committee which has been formed to carry out the Memorial.

Delphiniums and Tulips at Wembley.—We are informed that over five thousand Delphiniums have been planted in the grounds of the British Empire Exhibition at Wembley, and over one hundred thousand bulbs of the finest British-grown Tulips.

Snails and Plants.—In an address before the Royal Medico-Chirurgical Society of Glasgow, Professor F. O. Bower stated that some plants no doubt protect themselves from attack by snails by the sharp crystals called raphides which are embedded in mucilage. The latter, as well as the tissues, are gnawed, the cells rupture, and the sharp needles penetrate the delicate mouth of the marauder. Professor Bower stated that it has been shown by experiments that even hungry snails avoid plants so protected.

Appointments for the ensuing Week.—Tuesday, December 18: Sevenoaks Gardeners' Chrysanthemum Society's meeting; Winchester Horticultural Society's meeting. Friday, December 21: Eastbourne Horticultural Society's meeting. Saturday, December 22: Dumfermline Horticultural Society's annual meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*The late Mr. M'Nab.*—We have this week to record the decease of one of the oldest and best gardeners of whom this country has had to boast. Mr. William M'Nab, of Edinburgh, died on the 1st of the present month. An interesting history of his career is contained in the following extract from the proceedings at a public dinner given on March 14, 1844, upon the occasion of presenting him with the M'Nab Testimonial: "William M'Nab first saw the light in 1780, in the parish of Dailley, in Aryshire, where his father was a farmer. His early years were devoted to the duties of a shepherd on the hills of his native country. Amid those scenes, his genius was early directed to the beautiful forms and variety exhibited by vegetable life; and our stripling shepherd was inspired with a strong predilection for the occupation of a gardener. His father, yielding to his wishes, had him apprenticed to the gardener of Mr. Kennedy, of Dalquharran, at the age of sixteen. After serving three years in that place, he was recommended by Mr. Kennedy to the late Mr. Walter Dickson, of Edinburgh, who procured him a situation in the gardens of Lord Haddington, at Tyningham. There he remained about a year when, being anxious to improve still farther in his profession, he went to London, where he had the good fortune to be recommended by Mr. Aiton, superintendent of the Royal Garden at Kew, and to obtain employment in that magnificent establishment; after three years' service in the different departments he was appointed to the responsible situation of foreman. There he remained for several years, acquiring knowledge and experience; and here his conduct and intelligence recommended him to the favourable notice of His Majesty George III., then a frequent visitor at Kew, and brought him in contact with Sir Joseph Banks, the ready patron and judicious friend of modest merit. On the death of the curator of the Royal Botanic Garden at Edinburgh, the late Professor Rutherford consulted his friend Sir Joseph on the choice of a successor, and the baronet strongly recommended Mr. M'Nab, who immediately received the appointment and entered on the duties of his new office in May, 1810. It is therefore more thirty years since Mr. M'Nab was called to Edinburgh." *Gard. Chron., December 9, 1848.*

INDOOR PLANTS.

EVERGREEN SHRUBS WITH WHITE FLOWERS.

SOME of the most useful and interesting flowering plants for the decoration of the intermediate stove house, warm greenhouse or conservatory during several months of the year are to be found amongst shrubs bearing a profusion of white, fragrant flowers, that are set off by bright, evergreen foliage. Such white flowers are always in great demand for the making of floral designs. All of the plants described below are of easy culture, when the means at the grower's disposal are fairly good, and they may be increased readily by cuttings of half ripened wood placed in a hand light or frame with a moist atmosphere and slight bottom heat. During the winter a temperature of 55° to 60° is suitable, and the plants may be allowed to rest. In summer the temperature should be 60° to 70° with plenty of atmospheric moisture; in warm weather the plants should be shaded from the sun's rays. They all thrive in a mixture of good turfy loam, fibrous peat, or leaf mould in equal parts, with silver sand added. A free drainage is necessary to keep the soil sweet. When the plants are established and commencing to show their flower buds, give the roots liquid manure once a week.

Plants with pure white flowers are always attractive, and should have every care and attention bestowed on them. Unfortunately, during the past few years many of them have gone out of cultivation, excepting in a few places where a collection of indoor plants is still cultivated, or in botanic gardens. The following evergreen shrubs with white flowers comprise a select list: Acokanthera (syn. Toxicophlaea) spectabilis (see Fig. 124) is a warm house plant that produces large sprays of white fragrant flowers in spring. It is very floriferous, and even young plants flower freely. The blooms are very useful for the making of floral designs, being delightfully fragrant as well as pure white.

Gloneria jasminiflora is a very compact and free-growing extremely floriferous shrub, with pure white flowers. It is a charming plant for a warm house, and most useful for cutting purposes.

Coffea arabica, a pretty intermediate-house evergreen shrub, with bright foliage, produces white, sweetly-scented flowers in the autumn. Oxera pulchella may be grown as a climber or cultivated as a pot plant. It is of free growth, the ivory-white flowers being produced in large, axillary, pendulous clusters. This is a most valuable winter-flowering plant.

Thunbergia fragrans, a pretty trailing plant bearing white, fragrant flowers is very floriferous. It is suitable for growing in suspended baskets, or covering a wire trellis in a plant house.

Tabernaemontana coronaria flore-pleno flowers in winter and spring and requires the temperature of an intermediate house. Its clusters of fine white, double flowers are produced very abundantly, and they are set off by the neat, deep-green foliage.

Posoqueria longiflora is a very old evergreen shrub, bearing pure white, tubular, sweetly-scented flowers in dense clusters, It requires similar treatment to that afforded the Gardenia. Stephanotis floribunda Elvaston variety is far superior both in size of flower and truss to the type, and may be highly recommended. This is a beautiful, well-known, white-flowered evergreen climber most suitable for planting out in an intermediate temperate house, and the flowers are invaluable for cutting purposes for the making of wreaths and crosses or other floral designs.

A well-grown plant commences to flower early in the spring and remains in bloom continually until May or June. At that time it makes a considerable amount of growth and, where necessary, the shoots should be thinned. It is generally trained near the roof-rafters in a warm, moist, house. This exotic does best planted out, but it grows and flowers well in a pot with the shoots trained around a balloon-shaped trellis. It makes a useful plant when grown as single stem specimens and flowers freely. Plants in 48-sized pots will bear four to six trusses of flowers; the shoots should be trained over an arched stick. The value of such plants grown in this way for decorative purposes can scarcely be over-estimated.

The Stephanotis may readily be propagated from cuttings made of half-ripened wood and placed in a hand light or frame over moist bottom heat. Should the plant become infested with mealy bug it should be syringed at least once daily with diluted soot water, and occasionally with an insecticide. Mealy-bug may easily be kept in check if measures are taken as soon as it appears. Gardenias are amongst the most useful of plants we possess for furnishing cut blooms. They grow luxuriantly in pots plunged in bottom heat, in a warm temperature with plenty of atmospheric moisture. The bottom heat should be produced from fermenting material such as dung and leaves mixed; the warm, moist conditions of the hot-bed act as a preventive to attacks of insects. Syringe the plants two or three times during the day when the weather is suitable for spraying. When the plants are well rooted and commence to show their flower buds, a little liquid manure applied to the roots once or twice weekly will be beneficial to them, as the stimulant encourages the flowers to open freely. Where large numbers of plants are cultivated, they may, with a little extra attention, be had in flower throughout the year. When planted out they make fine bushes and produce a large quantity of flowers; having green, shining, leaves, they are a great acquisition to warm house plants. On warm days, a little air may be admitted to the house, but draughts and a dry atmosphere should be guarded against. Cuttings of half-ripened wood root freely in sandy soil in a moist bottom heat of about 70°, under a hand light or frame. Strong cuttings will give plants that will flower the same year as they are rooted. The soil for potting should consist of two-thirds good turfy loam and one-third fibrous peat or leaf-mould with silver sand added. The best species for general purposes is G. florida, a very free-flowering plant with fragrant white flowers and glossy green foliage. *John Heal, V.M.H.*

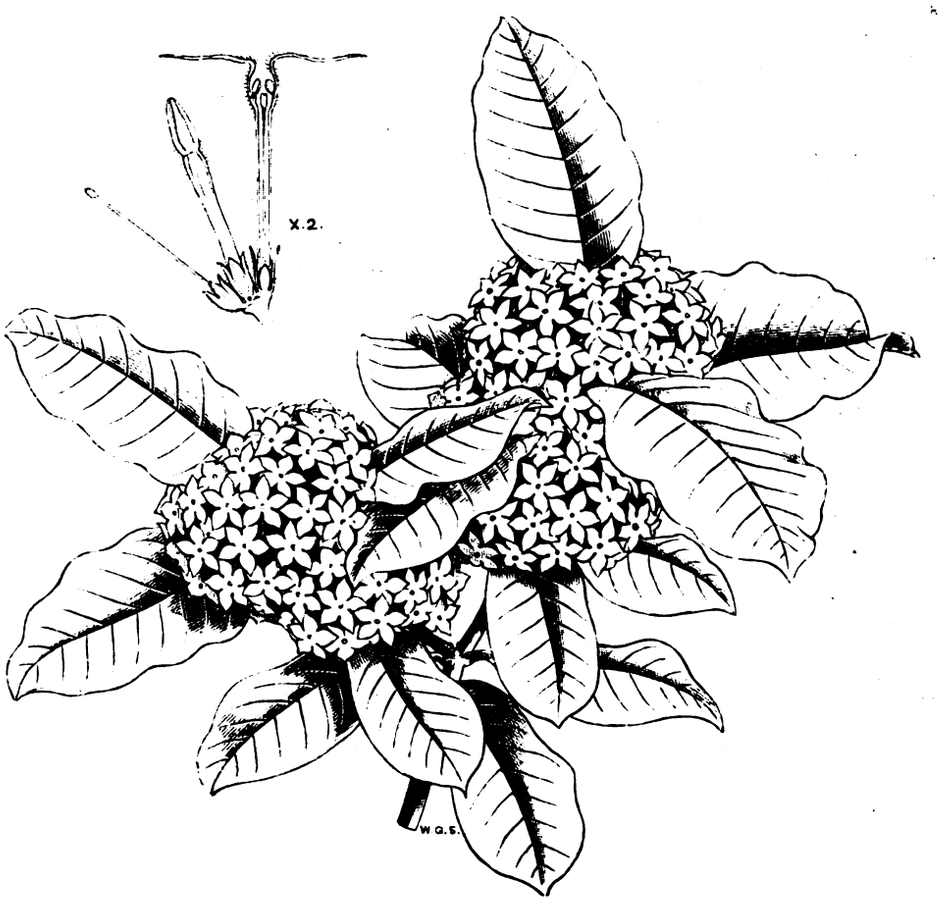

FIG. 124.—ACOKANTHERA (TOXICOPHLAEA) SPECTABILIS.

CESTRUM (HABROTHAMNUS) ELEGANS.

DURING the past two or three decades our gardens have been enormously enriched by the introduction of a large number of new plants from all quarters of the globe. This is all to the good, and adds to the joys of gardening, but is there not a danger of losing sight of some of the old, well-tried and beautiful plants that we loved in the closing decades of the last century? Such a plant is Cestrum (Habrothamnus) elegans, a winter-flowering greenhouse shrub of incontestable merit.

Introduced from Mexico about 1840 it soon became widely spread, and the fact that it flourished in a house of low temperature quickly made it a universal favourite for covering the walls and pillars of the cool greenhouse, for which purpose it still has few equals. Its red, elongated, tubular flowers, gradually widening to the top into a five-parted limb are borne in large clusters on long, slender branches clothed with alternate entire leaves, which are dark green above and downy on the under-surface.

For covering walls and pillars this Habrothamnus should be planted in a border and receive liberal treatment. It is also well suited to growing in pots. Cuttings struck in late spring, pinched several times and grown on outside during the summer make useful specimens for the decoration of the conservatory in winter. *W. Auton.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Sophronitis grandiflora. — This delightful Orchid is now in bloom; its brilliant flowers are always appreciated, and those who are fortunate in possessing choice varieties should take care of them, as undoubtedly they will become very valuable as time goes on. By using this Sophronitis as a parent, raisers have given us hybrids of rich colouring and great beauty. The flowers are produced on the partly-made pseudo-bulbs, and whilst in bud, care should be taken that no water lodges in the crown of the growth, as it might set up decay of the flower spike and new growth. Until the flowers are produced, the plants may be afforded water at the roots whenever they are seen to require it. Plants needing attention at the roots, are best attended to in the spring, when fresh roots are developing from the new growths.

Hybrids of Sophronitis.—The hybrids of Sophronitis grandiflora comprise plants of various characters; some being of small growth and others large. They have no particular season of flowering, as, owing to the different parents with which Sophronitis has been crossed, some one or the other is in bloom the whole year round, for this Orchid has been crossed with Cattleya, Laelia, Laelio-Cattleya, Brasso-Cattleya and others. The numerous forms mostly have flowers of vivid colours, whilst there are some with flowers of a yellow hue. In a family with such a varied parentage, it is obvious that constitutionally there is much diversity, but as I have pointed out before, a close observation of the different plants will soon teach one their requirements. Some of them have the character of being bad growers, but to my mind it is only a question of finding a place to suit them, and the ability to meet their requirements. The majority of them succeed in a light, warm position, in the Cattleya house, whilst the Sophronitis parent delights in the temperature of the cool or intermediate house. These plants are best grown suspended where no water from the syringe can reach them, and where they may enjoy all the light possible. They should be watered judiciously at all times, as the young growths decay and turn black if the compost is watered indiscriminately. Some of the hybrids have fine, and others thick roots. The thick rooting plants are generally of a more robust nature than those with finer roots, therefore they may be grown in larger receptacles, but over-potting must be guarded against in every case. The repotting of any of these delightful hybrids which have recently bloomed will be best deferred until the spring.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Pot Vines.—As soon as the vines have broken into growth satisfactorily the night temperature should range from 55° to 60° according to the weather, with a corresponding rise during the day. When the leaves appear raise the temperature by 5° both night and day. In favourable conditions admit air during the morning, closing the house at mid-day. The vines should be tied to the trellis soon after they have commenced to grow. Remove all weak and crowded growths at an early stage of their development. When the bunches begin to elongate discontinue the syringing of the vines, but promote atmospheric humidity by damping the bare spaces several times daily. To maintain a steady bottom heat it may be necessary to partially renew the fermenting material. Watering should be done carefully; keep the soil moist without saturating it. When the shoots attain a length of one foot a more liberal supply of water may be applied to vines in perfect health.

Early Muscat Vines.—If ripe muscat Grapes are required during the latter part of June this vinery may now be closed, and sufficient fire-heat used to maintain a night temperature of 50°, and 55° to 60° by day in mild weather. A mild hotbed placed on the border will stimulate root-action and obviate, to a certain degree, the need for artificial heat, which is an advantage. The condition of the border as regards moisture should be ascertained, and tepid water applied if required. Young rods should be tied down half-hoop fashion, so as to cause them to break regularly. Syringe the vines twice daily, and damp the paths and borders occasionally on sunny days. Where the roots are growing in both inside and outside borders, the latter should be covered with a mild hotbed of previously prepared fermenting materials; failing this apply a thick layer of freshly gathered Oak or Beech leaves, which may remain until warm weather returns, when it may be reduced in bulk by degrees.

Late Vines.—It will be necessary to examine late Grapes frequently with a view to removing bad berries. Muscats will need very careful treatment throughout this month and the next. If the bunches are shaded on the top with opaque paper, and a temperature of 48° to 50° is maintained, the Grapes will retain their freshness for a considerable time. Vines partially cleared of the bunches may have the remaining ones cut and placed in bottles in the Grape-room. This done the vinery may be thrown open, for plenty of cold air will be beneficial to the vines. If the borders are approaching a state of dryness they should be watered freely. Grapes such as Gros Colmar and Lady Downe's which are required to be kept as long as possible, should be allowed to remain on the vines for a month or five weeks longer before bottling them, keeping the vinery cool, and ventilating it whenever the weather is favourable for admitting air, but not on foggy and damp days.

THE FLOWER GARDEN.

By C. TURNER, Gardener to EMILY, LADY AMPTHILL Ampthill Park, Ampthill, Bedfordshire.

Lawns.—Where lawns have had heavy usage during the past season or the land is naturally on the poor side, some form of enrichment should be given to make up for the loss experienced. The top-dressing may consist of well-decayed farm-yard manure, old potting soil and a seven inch potful of bone meal to each barrow load of the compost. The manure should be broken as finely as possible, and then passed through a coarse sieve, adding the soil in the proportion of one part to every two parts of manure. Scatter the mixture evenly over the lawn and harrow it into the surface from time to time during the next two months or so. Should any depressions be noticeable these should be made level before applying the top-dressing.

Christmas Evergreens.—The securing of a supply of evergreens for Christmas decorations will occupy much time in most gardens during the current week, in addition to which there will be lengths of rope to be covered with short sprays of greenery for festooning purposes. For this latter use practically every kind of evergreen available should be secured to give variety and colour to the decorations. The supply of these evergreens should be taken from the back portions of woods and shrubberies as much as possible to avoid spoiling the frontal effects. Where it may be necessary, however, a little thinning of congested evergreen shrubs may be done anywhere by an experienced worker, even at this season of the year. On occasions one has to give ear to the cry of exigency before that of recognised custom.

PLANTS UNDER GLASS.

By JOHN COUTTS Assistant Curator, Royal Botanic Gardens, Kew.

Winter-flowering Begonias.—As these plants pass out of flower a sufficient number of strong healthy specimens should be selected for stock. In the case of the hybrids between B. socotrana and the tuberous-rooted varieties, as represented by Elatior, Optima, Mrs. Heal and Fascination, it is wise to retain plenty of stock plants, as they are by no means easy to keep over their resting period. The plants are best grown in a temperature of 50° to 55°, and water should at all times be carefully given at the roots. Aim at keeping the leaves in a fresh and healthy condition for so long as possible; as the foliage gradually dies off less water will be required, but at no time should complete drying-off be attempted. Frequent damping between the pots, and light sprayings rather than direct watering at the roots, will do much to tide them over the critical period. About the beginning of May they should begin to show signs of fresh growth; one may then regard the difficult period as being past. Some cultivators at this time resort to shaking the plants out, and replacing them in smaller pots with fresh compost; this I have not found necessary, unless it is desired to grow on some of the old plants as large specimens, for which purpose it is best to select young plants that were propagated late last season.

Begonias Gloire de Lorraine.—Begonias of this type do not, as a rule, present any difficulty. Plants selected for stock should be shortened somewhat, and kept on the dry side for a time, and later afforded more water at the roots. Young growth suitable for use as cuttings will then be produced from the bases of the old plants.

Other Begonias that flower during the winter include B. coccinea, B. Luzerna, B. fuchsioides, B. polyantha and B. Corbeille de Feu; they all belong to the evergreen or sub-shrubby section, and although most of them were commonly grown at one time they are seldom seen now-a-days. They are useful for furnishing the greenhouse during the winter, some of them, indeed, flower the year round.

Allamanda. — During the winter months Allamandas should be kept somewhat dry at the roots. While pot-grown specimens may, with advantage, be kept in a lower temperature, the warmth of the house should never fall below 55°. Where the strong growing species are planted out and trained under the roof glass, it may be necessary—for the sake of plants standing underneath them—to partly thin out the shoots, but the final pruning should not be done until January or February, when they should be pruned hard back, except such shoots as may be required for extension. With the exception of A. violacea, which should be grafted on young plants of the stronger growing species, Allamandas are easily propagated at any time by means of cuttings, plunging the pots in a close case with plenty of bottom heat. When they are are pruned back early in the year the ends of the shoots may be used as cuttings.

Solanum Wendlandii.—This handsome climber, where planted out, should be kept on the dry side during the winter. Plants in pots may be dried off and stored in a greenhouse, but the amount of drying off should be regulated by the age of the plants. Young plants with little or no old wood will not withstand so much drying off as older specimens. They should be pruned during February, when some of the more slender shoots may be cut into lengths of about four inches and used as cuttings, which will root readily in a warm propagating case.

Solanum Seaforthianum.—This is a much more slender growing species, and very useful for planting out in an intermediate house. It produces its pretty, pale, purple flowers more or less all the year round, and may be propagated at any time by means of cuttings.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Broad Beans.—The grower who has ample room under glass may obtain an early supply of Broad Beans by sowing five seeds each in eight-inch pots. Put plenty of drainage in the pots and use a compost consisting of good fibrous loam broken small, with a liberal addition of old Mushroom-bed manure. Three parts fill the pots with the soil, press the seeds edgeways firmly into it, and cover them by adding about an inch more compost. Water the soil and stand the pots in a vinery or Peach house, or even a cold frame will answer provided the plants are protected from severe frost. Broad Beans will not force, in the strict sense of the word, but young beans may be produced early in the spring if the crop is allowed to develop steadily and careful attention is given to watering, top-dressing with good soil, and staking the shoots when they require supporting.

Peas.—Good crops of Peas may also be produced by sowing seeds now in pots of eight or ten-inch diameter, using similar compost to that advised for Broad Beans. Make the soil fairly firm, sow ten or twelve seeds in each pot, and cover them with an inch of sifted soil. Water them, and transfer the seed pots to a cold house. The seeds will soon germinate, and as soon as the seedlings are large enough to handle, thin them to five or six in each pot. Grow the plants as near to the light as possible to prevent them becoming drawn and weakly, and as soon as they are large enough topdress them with some of the same soil. Place neat twigs in the pots for supporting the shoots. There are many varieties, both dwarf and tall, among the first earlies that will give good results in pots.

Lettuces.—Autumn-sown Lettuces will soon be past their best, Endive, Chicory, and Dandelion taking their place as salad plants. A sowing of one or two of the early and quickly-maturing varieties of Lettuces should now be made in a warm house. As soon as the seedlings are large enough they should be pricked out into boxes and transferred to frames on hot-beds. The non-hearting varieties may be pricked out in boxes and placed in a genial temperature. They will be ready for cutting before the hearting kinds as they grow very quickly, and, if kept fairly well watered, make a welcome addition to the salad bowl early in the spring.

Rhubarb.—Continue to lift small batches of Rhubarb roots and let them remain exposed to the air for a few days before placing them in the forcing house. The permanent beds should receive a good top-dressing of well-rotted manure; the winter rains will wash the nourishment down to the roots thereby greatly benefiting the crowns. The dung may be dug in when the beds are being tidied up before growth starts.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Orchard Trees.—The trees in old established plantations are usually of standard growth. With reasonable care an orchard that has not been too neglected may be brought into condition, to give a reasonable return. The first essential is to cut out the thick shoots that cross each other to let light and air enter the tree. Trees that are infested with lichen and insect pests should be sprayed with alkali wash after the work of pruning has been completed. The soil around the roots may need nourishment, either manure or lime; a good dressing of the latter is necessary in many instances. If the impoverishment is due to grass, it may be well to remove the turf about the bole of the trees to a diameter of 8 to 10 feet. Young trees will not thrive if grass is near them, but older trees are not so affected, only so far as a close or dense turf prevents a considerable amount of air reaching the roots. The work of repairs to fences, hedges, and boundaries of orchards may be undertaken when frost puts a stop to other work. Where rabbits abound the trees should be protected by wire netting to the height of about 4 feet up the stems. Where cattle are grazed in orchards, iron tree protectors may be necessary, and these should be inspected to see they do not injure the bark in any way. The iron-work will also need painting or tarring periodically. All trees should be labelled, and the wires by which they are affixed examined to see that they are not cutting into the bark.

Pears.—Self sterile varieties of Pears, as in the case of Apples, should be interplanted with free setters. These flower at the same time. The following varieties are suitable for providing a succession of fruit. Early: William's Bon Chretien, Beurré d'Amanlis, Louise Bonne of Jersey, Emile de Heyst, Beurré Hardy, Durondeau, Marie Louise, and Doyenné du Comice. Good late Pears include Beurré Diel, Glou Morceau, Beurré Clairgeau, Beurré Rance, Josephine de Malines, Le Lectier and Olivier de Serres. For rich, loamy, and heavy soils, Pears are best worked on the Quince stock, which has the same advantages as the Paradise Stock for Apples. Standard Pears should be grafted on the Pear stock.

FIG. 125.—BOENNINGHAUSENIA ALBIFLORA AT KENTONS, 1913. (SEE P. 351).

ALPINE GARDEN.

POLYGONUM SINO-CAPITATUM.

THIS is a very showy, prostrate-growing plant suitable for creeping over rocks. It has a curious combination of bronze and crimson colouring in its ovate leaves. It produces terminal heads of globular, soft pink flowers that are quite distinct. This plant needs to be grown in partial shade. *L.*

GENTIANA LAGODECHIANA.

MANY very beautiful Gentians have been introduced during recent years, and of these very few are of greater garden value than the subject of this note.

This magnificent Chinese species is very easy to grow, thereby differing from several other lovely Gentians; it appears to thrive equally in sun or in half-shade, provided the root-run is deep and cool. The flowers are produced at the extremities of the prostrate stems They are of good size and a brilliant deep blue in colour, with a little suspicion of green in the interior of the trumpet. Gentiana lagodechiana commences to bloom during July and continues to produce a succession of flowers until well into October.

Seed is plentifully produced and provides the best means of propagation. A mixture of loam, peat and sand, with a surfacing of stone chips suits this delightful plant, which needs the protection of a piece of glass during the winter but only if the weather is immoderately wet.

The flowers are of very long duration and a brilliant feature of the rock garden. *Ralph E. Arnold.*

[This plant received the R.H.S. Award of Merit on July 29, 1919, when shown by Messrs. Bakers, Wolverhampton. It was then regarded as a form of G. septemfida. EDS.]

CALANDRINIA UMBELLATA.

BIENNIAL in some positions, suitably placed in the rock garden or retaining wall, this bright little plant is a true perennial.

As this Calandrinia greatly resents transplanting, a few seeds should be sown thinly in small pots and the seedlings planted from the pots into their permanent quarters.

The brilliant magenta-crimson flowers are freely produced and wonderfully effective in bright sunshine; they are of long duration but remain closed during dull weather.

Planted in gritty soil on a rocky ledge or in the chinks of a wall, the plants take upon themselves a partially shrubby character and will thrive and flower over a number of years. Damp is the greatest enemy of this Alpine, therefore a position, such as the almost vertical face of a rock, or in a wall where some protection may be afforded against excessive damp, should be selected for the plants. Cuttings may be used for the purposes of propagation, but seeds germinate quickly and freely.

MENTHELLA REQUIENII.

THE names of some plants are exceedingly elusive, and this is one of these. In my early gardening days it was known as Mentha Requienii. Later we were informed that this was an error and that this tiny plant should be named Thymus corsicus. Now we are told that t should be termed Menthella Requienii. So far as regards its odour it is a Mint, with a pungent, yet delightful smell of peppermint, so powerful as to make one wonder that such a tiny plant could emit a scent so patent to all. But it requires adversity to bring out the possession of this virtue. As it carpets the ground or fights for existence among grass the tiny green leaves and the small blue or lavender flowers appear like a lichen's growth. Tread on it or touch it with the fingers and the perfume is apparent. It is a worthy little plant, which delights in a cool and damp nook where it will cover the ground closely with its leaves, which, about August, are decked with the tiny flowers already referred to. *S. Arnott.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

MARKET FRUIT GARDEN.

NOVEMBER, the best month for the planting of fruit trees and bushes, gave no suitable opportunity for this work. Rather more than the average rainfall for the whole month (2·63 inches on 9 days) fell during the first fortnight in my district, and then wintry conditions set in, the ground being frozen hard every night for the rest of the month. It is quite likely that there will be no chance of planting until February. However, there is much compensation in the fact that the frost must have done the land a great deal of good. I had several acres ploughed in readiness for planting, and there is no doubt that this will work down all the better, when the time comes, for having been subjected to hard frost. This is just what we have missed in recent winters, and the land has worked badly in spring as a consequence.

Progress with Pruning.

Work on the land being impossible, the horses have been usefully employed carting farmyard manure from a neighbouring farm, and the skilled hands have made good progress with pruning. There was a time when we were afraid to prune during frosty weather, and warnings against this practice are still seen from time to time in horticultural journals; but repeated experience has shown me that there is absolutely nothing to be feared. I have never seen the slightest harm follow pruning in any weather which men can tolerate.

I like to get the Plums pruned first. This consists almost entirely of cutting out dead wood; and there are many cartloads of it this year as a result of the severe attack of brown rot. It is promptly burnt, of course. Fortunately there is plenty of new growth to take its place. In the case of old Plums I leave the new shoots alone, except where they are crowded or interfering with others. The danger of silver-leaf makes it advisable to reduce the pruning of Plums to a minimum once they get to full fruiting condition. The trees should be shaped, as far as possible, whilst young, and then allowed to go pretty much their own way. There will always, unfortunately, be quite enough to do in the way of cutting out dead wood, which, in most cases, keeps the trees quite open enough.

When it comes to Apples I believe in lightly tipping the leading shoots of the old trees, as this keeps them growing. For many years the trees on my place, after the first few years of hard pruning to form the foundation, were allowed to go so far as leaders were concerned, pruning being practically confined to mere thinning out. This plan undoubtedly brings the trees quickly into bearing, and may be advisable for this purpose; but I think there should, at any rate, be a return to the tipping of leaders after the trees have been got into full bearing. Otherwise, on my rather poor land, they are apt to cease growing and to become a mass of fruit spurs. During the last two winters I have worked to get such trees growing again. The branches have been cut back to some kind of bud, almost dormant in most cases, and the tips cleared of fruit spurs for about six inches. In most cases this plan has been successful in producing a little growth, and it will be continued. On better land strong-growing varieties on free stocks may continue to grow quite enough without shortening the leaders, but for my conditions I believe the light tipping is advisable even for such a vigorous variety as Bramley's Seedling.

As for laterals, these are cut right back to fruit buds, where there are any, as is usually the case on old trees. Where there is no fruit bud the lateral is shortened to about five inches. Short spurring is strictly avoided, except in the case of varieties that make thin, twiggy laterals, and are liable to make too many fruit spurs, of which Allington Pippin is an outstanding example. My object is to make the pruning of old trees practically fool-proof, so that the ordinary hands can be put to it. Almost the only point on which they are required to show judgment is in deciding what laterals should be allowed to extend (treated as leaders) in order to furnish the tree with new branches. Here they are apt to fail, the tendency being to spur too many of them, with the result that the trees become too sparsely furnished at the tops.

The pruning of young trees can never be made fool-proof, judgment being continually called into play. A few men have an instinct for it; others can never be taught. I do this work myself as long as I can cope with it, which generally means until the trees are six or seven years old.

Pests and Diseases in 1924.

Present indications encourage the hope that pests and diseases will give less trouble next year than they did in the past season. Whilst pruning young Apples I have not found any eggs of the permanent Apple aphis, whereas last autumn many of the shoots were smothered. Several growers who have grease-banded their trees report a very light catch of winter moths, and I have observed none of the males on the wing. A few growers, however, report a full catch on grease-bands; so caterpillar trouble may be expected to be local next summer. I do not think that we often get two really bad aphis years in succession. One would think that the hosts of aphides about during the past season would be certain to lay enough eggs to ensure a severe attack in 1924; but nature in some way upsets the normal course of events. Possibly weather conditions may accomplish it, or natural enemies in the way of parasites. The latter are said by entomologists not to help us very much against aphides; but it seems to me that, though the parasites come too late to deal with a heavy insect attack before it has done a lot of damage, by the end of the season they have become numerous enough to make a clearance of the pests and so prevent a repetition of the serious attack in the following season.

Still more curious is the way in which fungus diseases fluctuate from year to year. Apple scab and brown rot of Plums have been very severe with me this season, and the weather throughout the year has been wet, and of a type, one would think, to encourage the spread of these diseases. Yet the young wood of Apples and Plums is now unusually free from scab and brown rot respectively.

It would be foolish, of course, to relax precautions on the ground of such observations; but I certainly expect 1924 to bring less trouble in the way of pests and diseases then its predecessor.

Organic Manures.

Few market growers nowadays are able to obtain as much farm-yard manure as they need for their trees, and town stable manure is much scarcer than it used to be, and never so good. This, no doubt, is one reason why so many growers are grassing their orchards and doing most of their manuring by grazing pigs beneath the trees There remain, however, plenty of cultivated orchards, for which a certain amount of organic manure is essential. Probably we can successfully supply any needed phosphate and potash in mineral form, but there seems to be no getting away from the call for nitrogen or ammonia in organic form, and the bulkier the source the better. Shoddy or wool waste always gives good results, and is probably the best substitute for farm-yard manure, though it is not a complete plant food, supplying nothing beyond nitrogen and organic matter, the latter in considerable bulk, since a fair dressing is 2 tons per acre, and the material is light if in dry condition. I like what is sold as grey shoddy, because it is in a finely-divided state, easily applied, which is more than can be said of all shoddy. This appears to be the actual raw wool, the dirty portions clipped off the fleeces. Some growers object to it because it contains a lot of weed seeds. I understand that these are of some species of Clover which grow in Australia, and I find that, though they germinate freely here, the seedlings soon die off in our climate. Castor meal is another organic nitrogenous material which I have used with success; but, although cheap on the face of it, if the price per unit of ammonia is worked out it is found to be rather high. Rather a favourite source of nitrogen with growers is ground hoof or horn. I have not tried this, as it seems to me that such indestructible stuff must be very slow in action, particularly as many samples are coarsely ground. However, its reputation is undoubtedly good, and I mean to try a finely-ground meal some day.

Meat meal and fish meal are largely used, and I have found them excellent, particularly for bush fruits. These differ from the materials already mentioned, in that they supply phosphates in addition to ammonia, and fish meal a little potash as well. If bush fruits can have farmyard manure every few years, they do very well with meat or fish meal in the intervening year.

Can we Pack too Well?

The Imperial Fruit Show at Manchester has revived interest in the subject of packing, and growers have again been blamed for not marketing all their best fruit in bushel boxes. Undoubtedly much more of this ought to be done for the big markets where there is a demand for Apples packed in this way. But I find that some of the provincial markets simply will not have it, or rather will not pay for it. The fact is that very many of the provincial markets do not make their own prices, but base them on report from Covent Garden. These reports give average prices, and not the prices which would be made by fruit graded and packed in an exceptional manner. The provincial salesman can get for his clients a little more than these average London prices, but if he goes too far above them it pays the retailers to get their supplies direct from Covent Garden, or opens the way for little wholesalers who hang about the market on the chance of buying produce cheaply and running it out to provincial towns on motor lorries. It works out that the grower cannot obtain more than a certain level of prices in a provincial market, no matter how well he packs; and, therefore, if he grades and packs any better than he need to secure those prices, he is simply throwing money away. I have always been an advocate for good grading and packing, and I box Apples for the London market whenever it pays me to do so; but it is still much more profitable to market the bulk elsewhere in half-sieves. Growers get all the blame for not adopting the boxing system, whereas quite as much belongs to the salesmen and retailers. The latter are popularly supposed to be ready

Digitized by Google

to jump at English boxed Apples in preference to those in baskets; but this is far from the truth. As things are at present boxed Apples meet the need of exceptional trade only, and it is not particularly easy to find a profitable outlet for them.—*Market Grower.*

PLANTS NEW OR NOTEWORTHY.

BOENNINGHAUSENIA ALBIFLORA.

BUT for the inexorable law which decrees that once correctly named a plant must always bear the title originally bestowed upon it, it is certain that the Rue whereof the beauty and floriferous character are so well portrayed in the photograph (Fig. 125), would long since have reverted to the pleasant name, Ruta albiflora, assigned to it by Hooker a hundred years ago, and of which it was deprived by Reichenbach in 1828.

The literature of our subject is scant, and if we take the most recent example, we find that Farrer* reports of Boenninghausenia that it is "a foot to eighteen inches high with sprays of the most ravishing small flowers, fine snow-white, all through the later summer It ranges from moderate elevations of 4,000 to 8,000 feet from Marri to Sikkim, and thence through those marvellous mountains of Asia across into Japan." From this we may conclude—did we not already know—that the species, which Farrer never saw in his Asiatic expeditions, did not prosper at Ingleborough, where he had his home, and that he was content to re-affirm Hooker's account of the plant.

The first mention of the species is found in Hooker's *Exotic Flora*,† wherein it is described and figured as a new species under the name of Ruta albiflora. Five years later, without apparently placing his reasons on record, Reichenbach,‡ possibly impressed by the obscurity of the generic character noticed by Hooker, removed the species from the Rue family and made a new monotypic genus of it, under the cumbrous title by which it has been known ever since. All we find in Walpers,§ is that Boenninghausenia grows in Nepaul, and Bentham and Hooker‖ gave it a range: "*Indiæ borealis montanæ et Japoniæ incola.*" Since then references to the plant have been few and far between, and that is the more remarkable in times like the present, when the virtues of plants are chronicled to such an extent as often to render their reiteration tiresome.

Under cultivation, Hooker's standard of height may become a yard and Farrer's "late summer" is often September and October, for the species is one of the latest of plants to bloom, and is regularly nipped by frost. In a backward season it may not commence to flower until about Michaelmas. The writer had several plants in his garden from 1903 till 1921, and beyond the fact that they were placed where the cold winds of spring could not reach them, they had to take the weather of those nineteen years as it came. The plants were frozen stiff several times during the period in question, and when that happened they generally lost their leaves, and much of the growth was cut some way back, only, however, to spring up again the following summer. The plants never received protection and did not seem to need it, even in the trying winter of 1908-9.

The specimen figured was about seven years old when photographed in 1913. It was then rather more than a yard high and as much across, and, fully exposed to the sun, grew in granite chippings mixed with equal parts of leaf-mould and a mere sprinkling of loam. It was over a subterranean irrigating pipe, and we may perhaps conclude that that may have had something to do with the fine growth of the plant. As it eventually outgrew its space, the plant had to be moved, and never recovered the operation, which, perhaps, was not done so carefully as would have been the case had it seemed difficult to cultivate. Of several other plants, two, growing under the same conditions, did as well as that shown in the illustration; the rest, in ordinary garden soil and without underground watering, did not prosper. The species is easily raised from cuttings, or seed, but the latter plan is to be preferred.

A. Grove.

* *The English Rock Garden*, Vol. 1, p. 145.

† Vol. '. Pl. 79 (1823). Ruta albiflora: plant woody and apparently perennial, about a foot in height, forming a small but handsome branching shrub . . . the whole giving out when bruised a smell similar to the Common Rue. This interesting little species of Ruta, so unlike all the others with which I am acquainted, in the general appearance and colour of the flowers has, nevertheless, the same structure of leaves and the same smell with the rest of its congeners. The number of parts in the species of this genus seems to be variable; but the stamens appear to me to be more frequently eight than ten. In regard to the generic character too, there seems to be some obscurity; at least, in the species I do not find "puncta mellifera," which are described as existing on the receptacle. There is, indeed, a remarkable gland or nectary surrounding the base of the germen, as in the other species of Ruta; but there are no distinct spots. The germen is pedunculated, which I do not find to be the case with other Rutæ, and the styles, though united so as to appear but one, are in reality four, or as many as there are lobes to the germen; and these are frequently separated as the lobes diverge in the capsules advancing to maturity. It is the only species with which I am acquainted that has white flowers. The plate is figured from a specimen in the garden of P. Neill, Esq., at Canonmills, in Edinburgh; it was raised from seed received from Nepaul.

HAKEA SUAVEOLENS.

THE flowering shoot of Hakea suaveolens illustrated in Fig. 126 was kindly forwarded by Mr. W. H. Honess from Viscount St. Cyres' Gardens at Walhampton, Hampshire. Mr. Honess states that the plant from which the shoot was taken is growing in a cool house, and is about five years old from the seed. Mr. Honess also states that they have a plant of Hakea suaveolens in an open border, where it has been growing for the past two years. This plant was recently subjected to frost of 20° and 18° respectively on two consecutive nights, and Mr. Honess is not able at present to state whether it received severe injury. It will be interesting, however, if he would communicate later how the plant behaved after experiencing such severe cold.

FIG. 126.—HAKEA SUAVEOLENS.

Hakea suaveolens is a Proteaceous shrub some eight to fifteen feet high and a native of Western Australia. The whitish flowers are produced in small clusters, as shown in the illustration, and apparently they are sweetly scented. The foliage is very elegant, and is somewhat similar to that of certain shrubby New Zealand Veronicas, and the leaves are as stiff as those of some Conifers, to which they bear no little resemblance: they are borne on erect, reddish barked stems

The specimen sent by Mr. Honess has remained perfectly fresh in water in our office for more than a week and shows no sign of withering.

A BI-GENERIC HYBRID: FATSHEDERA LIZÉI.

At the recent horticultural exhibition held in Paris (see *Gard. Chron.*, November 17, 1923, p. 298) MM. Lizé, nurseryman, Nantes, showed under the name of Aralia Lizéi, a very interesting plant, said to be the result of a cross between Fatsia (Aralia) japonica var. Moseri and the Ivy (Hedera Helix var. hibernica).

M. Guillaumin, of the Paris Natural History Museum, has studied the plant in question, and has written a note about it, which he read at the recent meeting of the Scientific Committee of the Société Nationale d'Horticulture de France. The plant shows a curious mingling of the characteristics of the Ivy and the Fatsia. It has the bearing of a Fatsia, but the stem is more slender and more branched; the medulla is like that of the Ivy, with secretory glands and regular, unpunctuated cellules. The leaves have from 3 to 5 lobes, as on the sterile branches of the Ivy; the petioles are long, with numerous libero-ligneous fascicles like those of the Fatsia; but there are no secretory glands in the sub-epidermic collenchyma, as in the Ivy. The flower-buds resemble those of the Ivy, and are equally hairy, unarticulated, with plain sepals, but having five distinct styles, like the Fatsia

The only characteristics intermediate between the two genera are (1) The texture of the hairs, which are starred (? rayed) and stiff in the Ivy; sparse, simple, or more rarely flexuous in the hybrid; (2) The shape of the disc which crowns the upper portion of the ovary is also intermediate in the hybrid. The stamens are always sterile and have no anthers.

One may thus conclude that this is really a bi-generic hybrid, and M. Guillaumin proposes that it shall be named :—Fatshedera Lizéi, Guillaumin (Fatsia japonica var, Moseri ♀ × Hedera Helix war hibernica ♂). *A. M.*

NOTES FROM A WELSH GARDEN.

Lithospermum rosmarinifolium has been a most beautiful object for some weeks, ceasing temporarily to flower only during the short spell of frost in late November. We have this fine subject growing in very poor, stony soil at the top of a low, dry wall in full sun, where it has made a spreading mass of its dense, rich green foliage. It is very seldom that this beautiful plant is injured by frost, although the blossoms are sometimes affected; but no sooner does the weather get milder than the intensely blue flowers expand as freely as ever.

Another bright spot in the rock-garden has been afforded by that charming little Daisy from Southern Europe, Bellis sylvestris. In general appearance and habit this pretty plant is much like our own field Daisy, but the foliage is larger and looser and the taller flower stems each bear a blossom that leans over, and whose white rays are tipped with a full rose-madder. That other delightful species, B. rotundifolia cœrulescens, with its distinct, grey-green foliage and pale bluish-lilac blossoms, which have been maintained in succession all summer, has only just ceased blooming.

With the approach of winter several of the Sedums develop that blue-white "bloom" which renders their foliage so attractive. Among these a few good and distinct forms of S. spathulifolium purpureum are most striking, the mealiness giving the red-purple rosettes a delicate dove colour. An old and distinct form of S. brevifolium (probably Pottsii) undergoes the same change, but in its case the white of the little round leaves assumes an electric-blue brilliance which is very effective. I think the charming S. Palmeri is more delightful at this season than at any other, as its pale yellowy-green rosettes now take on their glaucous winter sheen. Another member of the same genus which is at its best from autumn to late spring, practically going "out of business" in summer, is the little blue-grey S. amplexicaule.

In a half-shady place in the woodland Vinca difformis has been very lovely for a considerable time, and it still carries clusters of buds which will expand, as weather permits, throughout the winter. Though not unlike the Common Periwinkle (V. major) in foliage and habit this is a smaller and much less aggressive plant. In the form we have the flowers are a cold, icy white, with the merest tinge of blue. They are smaller than those of V. major and as the segments are sharply pointed to one side, they have that "whirling" appearance common to some of the smaller varieties.

Though the spell of hard weather, with the help of the birds, finished off most of the autumn berries, the Pernettyas are as gay with fruit as ever. The fact that they are thus left to remain in berry not only for the winter months but possibly until the new crop is appearing, should be sufficient to make these little shrubs popular with gardeners of all classes. But they are still quite uncommon in many localities. One rarely sees their fruiting sprays used for decoration in houses or shops at Christmas-time—a purpose to which they are admirably suited—and there are many uses in large and small gardens to which Pernettyas might be put, and which are now filled by shrubs of inferior merit.

The last of the Heaths to flower, Erica stricta, will not lose all its colour until E. darleyensis begins to bloom. Thus the former links-up the autumn with the winter-flowering kinds and these will "carry-on" to spring and so complete that chain of colour which the Heath garden maintains unbroken throughout the year. But E. stricta itself will be a subject of no little attraction for months to come, for its foliage is very distinct and its fine green affords a very telling setting for the bright rusty-red of the withered corollas which adorn the tips with delightful effect. Nor can one, in speaking of Heath foliage, pass-by without mention the warm coppery tint of Calluna vulgaris var. cuprea and the brassy gold of the variety aurea of the same species.

Arbutus Unedo and A. Menziesii never look quite so attractive as they do at this season in our woodland garden, the lustrous green of their beautiful foliage contrasting well with the brown of fallen leaves and dead Bracken fronds. The former, moreover, is furnished with both flowers and fruit, but although A. Menziesii has outstripped its neighbour it has not yet put forth a bloom.

Probably on account of the cold summer and autumn Fatsia japonica has not flowered with its customary freedom. Its bold, ivory-white knobs of blossoms are usually among the most striking features of the later autumn garden here. But this is, after all, a foliage shrub before anything else, and as such it would always be an object of distinction if it never produced a flower. Some specimens in a sea-coast garden a few miles away are nearly ten feet high, but the foliage undoubtedly loses colour by exposure to too much sun and such large leaves are ill-adapted to withstand wind. *A. T. Johnson, Talycafn, N. Wales.*

TREES AND SHRUBS.

EUCALYPTUS WHITTINGEHAMENSIS.

In the current issue of the *Transactions* of the Royal Scottish Arboricultural Society,* Mr. G. U. Macdonald gives an interesting account of an excursion made to Lord Balfour's seat at Whittingehame by members of the Society. In this account he refers to the famous Eucalyptus tree in these gardens, and states that its age is said to be seventy-one years, and its circumference about two feet from the ground is sixteen feet one inch.

Reference is made to this particular tree in the *Trees of Great Britain and Ireland* by Elwes and Henry, where it is given the name of Eucalyptus whittingehamensis. The following is an extract: "A tree raised at Whittingehame, Scotland, from seed which was probably obtained in Tasmania. This differs usually from typical E. Gunnii in the absence of glaucous bloom on the branchlets and the leaves of the adult plant. This tree is considered by Maiden, who has seen branchlets both of the parent tree and of its seedlings, to be E. Gunnii; but it does not match any of the specimens in the Kew Herbarium. It resembles E. acervula in the absence of the leaves; but has only three flowers in each umbel and bears different fruit. It is certainly not E. urnigera. Seedlings of the parent tree show considerable variation in the foliage, which in some specimens, together with the branchlets and flowers, is glaucous; and this points to a hybrid origin. Moreover, some of the seedlings at least are considerably hardier than the parent. I have not been able to make a study of the seedling trees in the fruit stage; but I suspect that the Whittingehame tree is a hybrid, with E. Gunnii as one of the parents. The peculiar urn-like shape of the fruit suggests the probability of E. urnigera being the other parent, though the tree at Whittingehame does not resemble the latter in foliage,"

Mr. Macdonald points out that particular attention was paid to four trees, growing in the policies, which were raised from seed from the foregoing tree. The young trees were five years old when planted in their present position, and their rate of growth is indicated below:—

No. 1.—This tree was planted in 1891, and is now 45 feet high with a circumference of 5 feet 3 inches, at 5 feet from the ground.

No. 2.—Planted in 1894, is 43 feet high, and it also has a circumference of 5 feet 3 inches at 5 feet.

No. 3.—Planted in 1898, is 40 feet high, with a circumference of 3 feet 10 inches

No. 4.—Planted in 1912, is 30 feet high and 19 inches in girth.

* *Transactions* of the Royal Scottish Arboricultural Society, Vol. XXXVII., Part II., November, 1923.

LEYCESTERIA FORMOSA.

Mr. Irwin Lynch's remarks on this flowering shrub, on page 259, both interest and surprise me He writes, "Although it does its best to live in various parts of the country, it is rarely seen in a satisfactory condition, except under very special circumstances or in localities at least as mild as Torquay." Leycesteria has been growing here luxuriantly for a number of years. I am afraid we have hardly appreciated it at its true worth, and have been inclined rather to look upon it partly as a nuisance, as the plant is continually springing up in places where it is not wanted. At first one was tender hearted and left such seedlings in *situ*, only to find that a year or so later they had grown so big as to be smothering other plants in their vicinity. They had then to be rooted out. Birds are evidently very fond of the berries and thus distribute the plant about the garden and elsewhere. Recently I had a good-sized specimen pulled out of a yard wall.

Though of subdued colouring the shrub is striking and graceful in appearance. The pendulous racemes remind me of miniature inverted pagodas. It is not the small white corollas which render the plant conspicuous; but the port-wine coloured fracts, and as these remain fresh after the corollas have fallen the shrub, from the gardening standpoint, has a long flowering period—throughout the summer and even autumn. The berries when miniature are of the same colour as the bracts. When ripe they take on a browner hue and become very juicy, with a skin so thin that they are apt to burst in pulling them off. The pulp has rather an evil odour, reminding me of that of sour milk.

We find the plants, which may reach a height of seven or eight feet, tend to get top heavy with age. Instead of supporting them, we usually root them out and put in their place chance seedlings which make good-sized plants the second season. It is true that severe frosts may cut back the shoots considerably, but they recover wonderfully. Probably it is a plant that likes abundant

Digitized by Google

moisture and usually there is little lack of rain here.

Mr. Lynch's remarks as regards planting this shrub for effect will have my consideration and I am grateful for them. *John Parkin, Blaithwaite, Wigton, Cumberland.*

FREMONTIA CALIFORNICA.

MR. AUTON states on p. 277 that Fremontia californica does not live to a great age. I would draw his attention to a fine plant at Leonardslee on the wall of the mansion, some 25 feet high with a stem girth ten years ago of 15½ inches. Whilst I was at Leonardslee, the tree was considered then to have been planted at least thirty or forty years. It flowered fairly well but never freely, and we experienced great difficulty in propagating the plant. We found layering the best method. *W. A. Cook.*

SPECIES OF PRUNUS SUITABLE FOR FORCING.

ON page 217 due praise is given to Prunus triloba for forcing, but I should like to bestow equal praise to the single form of this Peach, not that I have seen it as a forced plant, but I see no reason why it should not force more readily than the double form.

Grown naturally out-of-doors it has a bushy habit; the rich pink flowers appear earlier than those of the double one and are of simple charm for decoration. As growth is twiggy on the old tree no doubt the shoots would be long and strong if the plant were pruned hard back after flowering. With further reference to the double form, Prunus triloba var. flore-pleno, it is as well to mention that it is prone to Silver-leaf, and considering the great number of trees sent out by nurserymen they should take heed that stock is propagated from the healthiest plants.

There are other species of Prunus which I am certain would meet with approval if forced; they may have been used for this purpose, but I am not aware of it.

Take for instance Prunus Conradinae, which in ordinary seasons out-of-doors flowers during February. Judging from this fact but very little fire heat would be required to have it in flower for Christmas.

Prunus Conradinae out-of-doors grows strongly and makes long arching growths; the twiggy wood is crowded with blush tinted flowers disposed along the branches at flowering time.

Prunus pilosiuscula, another recently introduced Chinese species, should be added to the list; it has a different habit to the aforementioned as it is more ascending, having pink flowers densely clustered on the short twigs.

Another very fine Prunus which so far appears to have escaped the attention of growers is Prunus incisa, a Japanese species very near to P. subhirtella, especially in the colour of the flowers, which are of a pleasing shade of pink. Both kinds in the early spring are almost smothered in flowers. Prunus incisa differs from the other in being earlier to flower, stiffer in habit and less in size; it also sets fruit each year whereas C. subhirtella scarcely ever fruits in this country; the fruits of both are shining black and smaller than Black-currants. Prunus subhirtella is by now very well known and by some must have been tried as a forced tree, but it is worthy of being grown extensively for forcing, although for this purpose there is no need to have both species. Established trees out-of-doors are unequalled for their beauty when in flower. Both the white and pink-flowered forms of Prunus Davidiana should be introduced to the earliest Peach to flower out-of-doors. It has a splendid habit, grows fast, soon makes a good bush, and lends itself splendidly for early forcing and as a conservatory plant.

Although I base my remarks on trees that I have seen growing out-of-doors I am sure of their success for the purpose indicated. *C. F. C.*

BULB GARDEN.

GLADIOLUS PRIMULINUS HYBRIDS.

I HAVE gone through the chronology of the modern Gladiolus from the days of long ago when Dean Herbert first experimented with some of the then known species in his garden at Spofforth, and saw enough to be able to say, "I am persuaded that the African Gladioli will become great favourites when their beauty in the open border, the facility of their culture and the endless variety that may be produced from seed by blending the several species are fully known; nor will they be found to yield in beauty to the Tulip and Ranunculus": I have, as it were, heard the marriage bells of G. psittacinus and G. cardinalis, and taken part in the rejoicings over their first born G. gandavensis in 1841; I have noted the coming of G. purpureo-auratus in 1870, followed by the birth of G. Lemoinei in 1875; I have, so to say, been on the quay-side when a year or two after G. purpureo-auratus, came G. Saundersii, and I have its beautiful children, G. Nanceianus, the first born (1889), and a little later G. Childsii; then came G. princeps.

Last of all Africa sent us in 1904 from the Victoria Falls on the Zambesi G. primulinus. Fortunately for us it is not only a great beauty in itself, but it has that strange subtle power, whose possession ranks in Mendelian language as a "dominant," which in this case means that it is able to impose something of its own clean yellow colouring and its curiously shaped top petal on all its offspring. Again, fortunately for us, it has been found to be at least as hardy as the older sorts and its progeny equally so, in fact I have been told of a few boxes of seedlings that stood out-of-doors in the open all last winter and were none the worse for it, but one has to remember that it was the antithesis of the type we label "good old-fashioned." Two sets from Messrs. R. H. Bath this last autumn have enabled me to enjoy a large number of the most beautiful flowers. There were no mauve or purple shades amongst them, and I cannot recall having seen any at shows, but the list of different colours or shades was a long one. In Ridway's colour chart nomenclature there were examples of peach-red, eosine-pink, Begonia-rose, orient-pink, capucine-orange, sulphur-yellow, scarlet, pinnard-yellow, thulite-pink, shell-pink, Geranium-pink, light greeny-yellow, spectrum-red, orange-pink, and flesh-pink. In the way of colour the influence of G. primulinus is much the same as that of the lightly stretched nets before tableaux vivants. It is a great softener. It is their exquisite softness that is one factor in the wonderful charm of these hybrids. A second factor is their petitness. Their stems are thin; their flowers are not over large and they are gracefully placed on the stems, with spaces between; they remember the past and the part that that distinctive upper petal has played in the preservation of their race amid the spray of the falls and it is displayed with pride.

I have written "are (' and "is," but I seem to see in the seventy-times-seven sailing over from the States, and swooping down upon this sea-girt isle from our neighbour on the far side of the North Sea, symptoms which suggest that ere long "are" and "is" will have to give place to "were" and "was." It was a sad report that I got from a very famous gardener after one of the R. H. S. meetings, when many G. primulinus hybrids, as well of course as other types, were staged "coarse beyond belief." Poor hybrids, are all your charms to be "butchered to make a Roman holiday?" I fear, if straws show how the wind blows, and if coming events cast their shadows before, that indeed it may be so. But may such a calamity be averted. If all our hybrids may not be Nydias and Woodcotes, let us hope that there will always be a remnant left which have not bowed the knee to Baal.

Among the most attractive of the true primulinus-shaped hybrids may be mentioned Woodcote (coral red), Nydia (blush), Souvenir (yellow), Elberton (cream), Eden (pink), Eurydice (rose), L'Yser (orange-scarlet), Nightingale (soft rose), and Orange Brilliant (orange-scarlet). Of those that are not so near the type Alice Tiplady (orange), Ming Toy (salmon), Latonia (rose), Walter Bloem (scarlet), and Sunrise (yellow).

Many of these above are high in price, but where these primulinus hybrids have been coming to the front, we have found how easy and simple it is to raise our own seedlings. Firms which make a speciality of them sell seed, and (this is good news) I am assured by Mr. Gibson, of Messrs. Lowe and Gibson, that if the seed is sown in late January about 20 per cent. of the seedlings may be expected to bloom in the same year. I am going to make the experiment myself. A warm house is necessary, and the seed must be underground before the 7th of February. Margarine boxes are handy receptacles. The seed should be sown thinly, for the young seedlings should not be moved until they flower, but be kept steadily growing on under glass until they bloom in September or October. There should be good drainage provided, and over it a rich, porous rooting medium, covered with an inch-and-a-half of light soil to receive the seeds, which should be placed about half-an-inch below the surface. Out-of-door sowing should not be made until late March or April, according to the district. Flowers must not be expected in the same year from such sowings, nor from sowings made in a cold house in February or March. Flowers are only obtained in the same year when the early sowings are made in gentle heat. *Joseph Jacob.*

THE MIXED FLOWER BORDER.

(*Concluded from p.* 339.)

In planting, the individuality of the subjects ought to be consulted. I have seen it recommended to set out all plants in triplets. It is an easy way of disposing of a matter that obviously demands more consideration if justice is to be done to the qualities of the plants, and the requirements of the whole. For there are some that in an extensive border may be arranged in tens, and others that give their best effect in single isolation. A well-grown Kniphofia or a Delphinium is representative of the one, and the Hollyhocks, Larkspurs, or Carnations of the other.

Nor must we forget the pleasure of the looker-on may be increased by variety. Colour is not everything. It is much better to have white, for instance, in a variety of distinct plants than in those of the same species. How much to be desired is it to have a white Campanula and Perry's white Achillea, a white Aconitum autumnale, Galtonia candicans and white Carnation, than a variety of white Phloxes—beautiful as they may be.

The question of support to herbaceous perennials is of consequence on at least two counts. Staking demands much labour, and at best it is of no advantage to the border as a whole. All that can be said of it is that there are plants that must be supported; but where it can be omitted—and means for obviating it can be used—then such should be made use of. I often see plants staked that need no support. Some merely need a string tied around them to keep them steady, combined with the support of other plants near or almost touching them. And there are others, which by a judicious trimming in June, are kept dwarf, and, therefore, independent of the help of the stick they would otherwise require. Moreover, there are plants pretty enough, but with an Uriah Heep disposition which it is as well to exclude from the garden altogether. Such is Crucianella—now, I believe, dubbed Phuopsis—stylosa, and Polygonum vaccinifolium. These are not the worst offenders either, but they will serve as illustrations..

Digitized by Google

What is to be done with the moisture loving plants, Astilbe Davidii for instance? My experience with these is that an extra supply of rotted cow dung, and keeping the plants young by frequent division almost meets the case. I write "almost," for when a period of drought bad enough to affect other plants comes, these too are badly affected. So then, water, if it can be had, must be applied. With regard to watering generally, it should not be too long delayed, first of all applying water to those plants that first exhibit signs of exhaustion, which often will be enough. And pure water is certainly not nearly so efficacious as that strengthened by some efficient manure.

The border I have in mind is not a one-colour border, nor a border of various flowers shading from one colour to another, but a border of mixed colours, which is more difficult to arrange than either of these. It is found that white used with restraint is a great help in overcoming colour incompatibilities, and perhaps even better than white is a free use of grey, of which there is a choice ample enough to meet any exigency. I will name only Cerastium Biebersteinii, Cineraria maritima, Lychnis Agrostemma, crimson, or the white-flowered variety—one of the choicest border plants. Almost too lowly to mention is common Wormwood (Artemisia Absinthium), but certainly a decorative plant of great value when well treated. Santolina Chamæcyparissus is also good, and Lavender, selected for its greyness. I would even try Teucrium fruticans where the climate is propitious, and Eryngium giganteum can scarcely be left out.

Annuals and biennials, however lax may be the choosing of the permanent plants, must be selected with the utmost care, and florists' flowers similarly. Probably, beautiful as Gladiolus are they may be dispensed with, or only a clump or two of such telling sorts as Prince of Wales, Chris, General Foch or Czar Peter introduced.

Pyrethrums again should always be used with great caution, or not at all. Of Carnations, I would select Grenadier as almost indispensable; Raby Castle, Mabel and Dom Pedro, are also valuable. Dahlias may be represented by the Pompon sorts, Nerissa and Darkness, a few of the tall Decorative section and Coltness Gem.

Annuals may be admitted among perennials because they provide colours not only distinct from the latter, but also, if anything, more refined and beautiful. Thus, in blue, we have the lovely Cynoglossum amabile, blue shades of Stock-flowered Larkspurs, Miss Jekyll's variety of Love-in-a-Mist, mauve Scabious and China Asters, to mention no others. In yellow there is nothing finer than a first rate strain of African Marigolds which, however, should be grown apart until in flower, when the double-flowered forms may be selected for groups, and the no less attractive orange-coloured singles similarly disposed of. Then, what is so charming as a bold group of Tagetes pumila signata, or so distinct as Golden Gem Matricaria? There is room also for the very tall, pure yellow Antirrhinums, and so in other colours, always, however, restraining oneself in the choice so that only the very best is selected. Personally, I have no objection to the lowly bedding Lobelia, if it be Waverley Blue, or of a good bedding Begonia, or a Verbena of character. But, of course, here again there must be restraint.

Nothing is more important than the removal of decaying flowers. It is not enough to wait to remove the seeded parts when the plant has become strained in their production. No; the only perfect method is to remove the inflorescence when a few of the flowers have seeded. The plant will then, in fertile soil, go on producing more flowers, and, if not, it will maintain its position of respectability among its neighbours, while the jaded seed-bearer never overcomes its condition of semi exhaustion and disreputableness. In a word, it continues an eyesore till cut down. *R. P. Brotherston.*

VEGETABLE GARDEN.

BROAD BEANS.

LOVERS of the wholesome and highly-nutritious Broad Bean will do well to make their first sowing on the first fine dry day, and to choose a fairly strong soil in a warm, sheltered position, the object being to obtain well-developed plants before the spring droughts set in. A thin sowing of well-developed seed is strongly recommended, as poorly developed and overcrowded plants fall an easy prey to drought and the pestiferous "Black Dolphin," producing, in any case, an unprofitable and unsatisfactory crop.

The Broad Bean is distinctly European in its origin, and its developments are of a well-fixed character. This is shown by the fact that of the eight varieties quoted in the catalogue of Drummond, Edinburgh, for 1750, one-half are the popular varieties to-day, and the remaining four are also quoted under "up-to-date" names On the contrary, of the twenty-six varieties of Peas quoted by Drummond, only one variety (Dwarf Sugar) is quoted in seed catalogues to-day.

It is somewhat remarkable that a vegetable which is held in such high esteem from Seville to Iceland should be considered as mainly a poor man's food in Great Britain. Truly the poor man is to be envied in being provided with a plant which is easily cultivated in our proverbially trying climate, and which, in the flowering stage pleases the eye by the form and colouring of its beautiful and numerous flowers which perfume the countryside with their agreeable odour, and in its fruiting stage presents him with a nutritive and pleasant food when young and tender, and a solid and lasting nourishment when old and dry.

As regards the latter point, the testimony of Jas. Justice, F.R.S., in 1754, may be interesting. "The Green Genoa Bean I allow to be quite ripe before I gather it for winter use. After they were dried, I steeped them in water for some days to soften. If you boil them with bacon and fowls they not only retain their colour but eat as well as in summer." As regards the development of new varieties, it is rather remarkable that they have been neither numerous nor distinct either in colour or form, but mainly amplifications of properties and qualities already in existence. The variety, Green Harlington Windsor is an exception to this rule, as it displays the colouring of both parents with the form of the white variety. It should properly have been named Greenish Harlington. It was first offered about 1866 under the name of Westbury Prize, it having appeared as a natural sport in a market garden near that Wiltshire town. To-day it has a larger sale than any other Windsor variety. Messrs. Sutton and Sons have recently exhibited some interesting and promising hybrids, which, when thoroughly fixed in character, will be welcome additions to the table of rich or poor. Beck's Gem, one of the most interesting varieties, itself a natural hybrid, sent into commerce by the introducers of the Westbury Prize, is a prominent feature in the Sutton hybrids.

In reply to the question which is the best variety for earliest open air sowings, opinions are somewhat divided, some holding with Justice who states: "The Mazagan, grown from seed obtained from Lisbon, is one of the earliest kinds which I prefer, because it is a very great bearer and has a fine taste," while others, like Mr. Edwin Beckett, pin their faith to the Aquadulce. In my opinion Bunyard's Exhibition, which combines the merits of the Spanish types with greater hardiness and purer strains of the English varieties, takes a lot of beating for earliness, quality and crop.

For forcing, the dwarf white Fan, and its offspring, Beck's Gem are invaluable.

For a main crop, choose any of the improved strains of white and green Longpods, and for latest crops Taylor's and Harlington Windsor, greenish and white, may be relied on. *S. B. D.*

MARKET APPLES.

THE articles by *Market Grower* are always interesting and practical, and it is seldom that I do not feel able to endorse everything that he writes: yet I disagree, to a very considerable extent, with his remarks on p. 297, when he advises those who may be raising new Apples to study colour before other considerations. There is not the slightest doubt but that the unthinking are apt to be attracted by colour for a time, but even they, in the end, will not buy poor Apples for their colour alone.

This year Apples have been scarce, and rubbishy fruits have sold at good prices. Green, sour windfalls have realised sixpence per pound retail in my town, and it is not surprising that *Market Grower's* Fearn's Pippin sold so well, but I am glad to know that the public is becoming every year more alive to real quality in Apples. This autumn excellent York Imperial Apples from America have been available; this is not a red Apple but the local retailers found it their best seller, and I am not surprised as it comes very near to our best Blenheim Pippin in intrinsic merit. Could we grow Apples like these in quantity we need not worry about import duties on fruit. Many imported Apples are yellow, not red, but they sell on their merits, and the public has discovered that these imported Apples require but little sugar when cooked and that most of them are as good for dessert as for culinary use. York Imperial is an excellent cooker, free from excessive water in the final result in an Apple pie. I do not know whether we can raise in this country Apples of the type that reach us from overseas, sweet and clean and prolific in yield, but I fear our climate is not sunny enough taking an average of years. Apart from Blenheim Pippin I can hardly name a first-class English market Apple that is healthy and prolific and delicious either cooked or raw. Blenheim Pippin when well grown is a noble fruit, and an Apple that a salesman is proud to handle.

It may not be impossible to combine colour and quality in an English market Apple, but if raisers took as much pains to evolve good new Apples as they do to evolve new flowers we should be rewarded with success, unless our climate is hopeless, which I do not believe, seeing that we grow a few sorts such as Blenheim Pippin and Cox's Orange Pippin to perfection. *W. J. Farmer.*

FRUIT REGISTER.

APPLES FORGE AND NANNY.

THESE two old varieties of Apples are so extensively cultivated in Sussex that they are usually described as of Sussex origin; but if the statement made by Mr. G. Chawley, of Coasters Nursery, Midhurst, Surrey, in Barron's *British Apples*, is correct, Nanny appears to have been raised in Surrey, for he states (p. 42) specimens he exhibited at the National Apple Congress, held in the Royal Horticultural Society's Gardens at Chiswick in 1883, were gathered from the original tree. Forge, according to Hogg, in the *Fruit Manual*, originated at Forge Farm, near one of the old forges in the iron districts of Sussex, near Crawley. Mr. Joseph Cheal, who brought a dish of both of the varieties illustrated in Fig. 127 to the meeting of the Royal Horticultural Society on November 13, states it is one of the most popular Apples in Sussex, and that it is used there both as a dessert and culinary variety; but Hogg describes it merely as a kitchen Apple. The fruit, as will be seen on reference to the illustration, is of medium size and roundish in shape; the skin is streaked with

Digitized by Google

orange-red. The tree is a prolific bearer, and the fruits are of excellent cooking quality.

Nanny, whatever its origin, is most largely cultivated in Sussex, for Mr. A. E. Bunyard in *A Handbook of Fruits* states that it is not commonly met with in other parts of the country. Hogg describes it as a dessert Apple of excellent quality, and when in perfection a first-rate fruit. He also states that the flavour bears some resemblance to that of Ribston Pippin, and describes the tree as a better bearer than that variety. The flesh is tender and of a greenish-yellow colour. The skin also is greenish-yellow, freely streaked with red on the shaded side, and bright red, streaked with dark crimson on the side next to the sun. In Messrs. Cheal's catalogue this Apple is stated to be worthy of inclusion in every collection. Those who are planting Apple trees this season should not overlook the merits of some of these free-cropping older varieties, as they would serve as pollinators to self-sterile sorts, besides giving profitable returns.

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Phygelius and other Things.—I was recently in the Carse of Gowrie, and took the opportunity to call on Mr. Maxwell of Errol Park, where among other good things I found Phygelius capensis established and thriving in one of the borders. I thought it worth noting that a plant that is not hardy enough to withstand wintry weather several hundreds of miles further south should be happy here on the north side of the Tay. Near-by was a representative of another genus that dislikes our Scottish winters, Kniphofia Saundersii, with a crop of its striking orange spikes, and clumps of Anemone pulsatilla in unblushing luxuriance gave evidence of the quality of the soil, for cold is not its bane. But from the exuberance of the growth of all kinds of vegetation, from monster Yews to humble Leeks, one might well conclude that soil and climate are alike very good. Mr Maxwell attributes much of the freedom of the estate generally from weather disabilities to the grounds standing on a big knoll, and it must have been a wise hawk that chose this particular spot, and secured to its earliest owner, the first of the Hay's, this pleasant spot for his possession. I had a stroll through the pleasure grounds and saw the quaint, sunk, oval, bowling green, the long line of ancient Yews the notable deciduous Cypress (can this be the Abor Vitae that attracted Pennant's attention?) and other fine trees. I had also a look into the Apple room, and unlike so many fruit rooms where there are no Apples, here was abundance of very fine fruit, and probably the finest Cox's Orange Pippins in Scotland. But the Carse is famed for Apples and Pears and I was sorry to know that the old orchards of Golden Knaps, Carnocks and others are slowly dying out all down the Carse. The glass department at Errol is notable for its corridor, the back wall whereof is clothed with a fine selection of climbers. Cyclamens and Cinerarias were present but the plants that appealed most to me where the Carnations, in the most perfect health, and with unspotted foliage. So here was something that soil and climate had not much to do with. Unfortunately I did not see everything. For one of my companions, womanlike, asked me afterwards, "Did you notice the door handles"? I had to confess I did not. But I had seen door handles elsewhere rubbed as bright as these while the inmates of the houses were by no means as well cared for. I was pleased to see a garden unspoiled by pergola, stone-paths and other modernities that some people take for gardening. *R. P. Brotherston.*

The Garden Heath. — Your correspondent, *W. Auton* gives an excellent list of Ericas on p 293. I would draw attention to two of the best Heaths which he has omitted, viz., Erica Veitchii, said to be a cross between E. arborea and E. lusitanica (codonodes), and E. arborea. E. lusitanica is one of the best of the family and is extraordinarily free in flowering. The plant presents a very conspicuous feature used either as dot specimens in the border or massed in a bed—especially in a Sussex or Surrey garden. The other species Erica arborea —or Tree Heath—from the Mediterranean region is a beautiful plant and is, moreover, Almond scented. It comes into flower later than E. lusitanica. Clumps of this Erica are most pleasing, especially for the fragrance. Both the Heaths I have referred to may be raised from seed very quickly, in fact one often sees young plants growing naturally from seed under the old plants where the ground has not been disturbed Erica Mackayi var. fl. pl. is a pretty dwarf Heath. It is found in Ireland and Spain and is well worth a place in any collection of Ericas. *W. A. C.*

Veronica salicifolia. — My experience of Veronicas is that there are only three sorts really hardy and that on the East Coast, a severe frost destroyed V. salicifolia with other not quite hardy shrubs; it did not merely cut the plant down but killed it, root and branch. Seedlings supplied at a later date took its place. *R. P. Brotherston.*

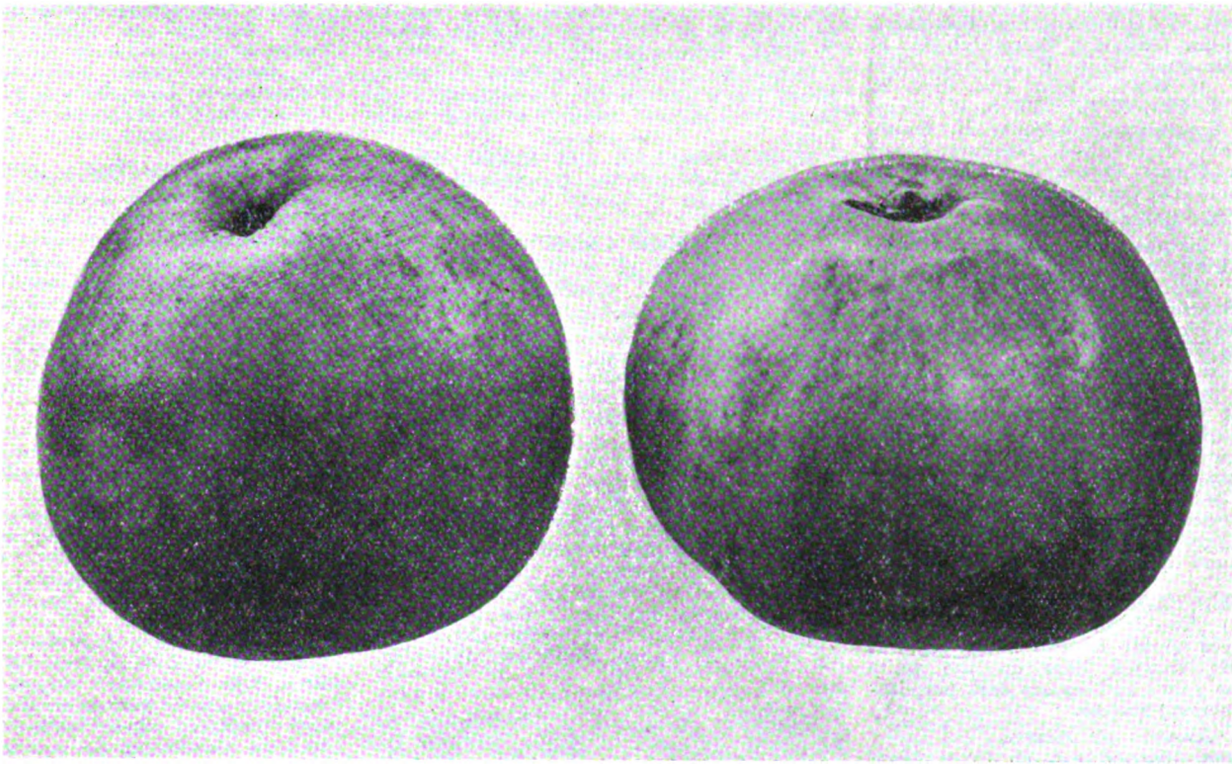

FIG 127.—TWO OLD SUSSEX APPLES: FORGE (LEFT) AND NANNY (RIGHT).

APPLE BROAD-EYED PIPPIN.

THIS splendid culinary Apple, to which reference is made on page 327, is well known in some parts of Herefordshire, and it is surprising that it is not more extensively planted, the fruits being of large size and of rich colour. This variety is obviously of great antiquity as many of the trees I have seen are well over one hundred years old. It is a persistent cropper and specimens of this Apple, quite sound, have been brought for my notice in the month of March. The fruit is large and oblate in shape. The skin is greenish yellow, faintly streaked with red, and with bright red and darker coloured streaks on the side next to the sun. The eye is large and open and set in a wide and shallow basin. The flesh is yellowish-white, firm, crisp, brisk and juicy.

The bastard Blenheim is known in Herefordshire as the Dewsan Apple, a synonym of Hambledon deux Ans, of which large numbers of trees are distributed in many orchards on the Ross side of the county. *Pomona.*

SOCIETIES.

ROYAL HORTICULTURAL.

DECEMBER 11.—The concluding meeting of the year is never remarkable for the extent of the exhibition at Vincent Square, and the one on the above date was no exception. There were comparatively few exhibits of flowers and plants, but considerable space was occupied by paintings, garden plans, photographs of garden scenes, and garden sundries.

The chief attractions among plants and flowers were the Orchids, Chrysanthemums, Carnations, and hardy shrubs. Among Orchids, the wonderful Cypripediums from Mr. G. F. Moore were the outstanding feature, and the fact that he has gained seven First Class Certificates at two meetings is evidence of the splendid size, form and colour of his seedlings.

The Orchid Committee made awards to five Orchids and three groups; the Fruit Committee made no awards; and the Floral Committee granted an Award of Merit to a Chrysanthemum, and medals to ten groups.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Messrs. J. O'Brien (Hon. Secretary), Gurney Wilson (Assistant Secretary), G. F. Moore, R. Brooman White, C. J. Lucas, Clive Cookson, W. H. White, Arthur Dye, Fred. K. Sander, H. T. Pitt, J. E. Shill, S. W. Flory, J. Cypher, T. Armstrong, Henry H. Smith, E. R. Ashton, Frederick J. Hanbury, Stuart H. Low, J. Wilson Potter, J. Cypher, Chas. H. Curtis and Dr. Craven Moore.

FIRST CLASS CERTIFICATES.

Continuing his phenomenal success of obtaining four First Class Certificates at the last meeting for Cypripediums, Mr. G. F. Moore, Chardwar, Bourton-on-the-Water (gr. Mr. Page), secured three similar awards on this occasion. The varieties were as follow:

Cypripedium Chrysostom, Chardwar variety. (*Christopher var. Grand Duke Nicholas* × *Pyramus*). This variety has a very large dorsal sepal, white with purple lines, and broad petals; the lip is honey-yellow marked with red-brown.

Gwen Hannen, Chardwar variety. (*Florence Spencer* × *Christopher*). A massive flower with broad, white dorsal sepal with spotted lines on an emerald-green ground on the lower half. The petals and lip are tinged with mahogany-red.

Prince Albert, Chardwar variety (*Tommy Curte* × *Pyramus*) The darkest of this fine section which has yet appeared. The dorsal sepal is mauve with claret-red lines on the white margin. The petals and lip are dark purplish-red with a shining surface.

AWARDS OF MERIT.

Cypripedium Warrior var. H. Green (*Lord Wolmer* × *Alcibiades*), from Messrs. ARMSTRONG AND BROWN, Tunbridge Wells. A model flower from a new batch and which promises to develop into a superior form. The broad, circular dorsal sepal is pure white with a greenish base heavily spotted with dark claret colour; the petals and lip are yellow tinged with claret-red.

Sophro-Laelio-Cattleya Eileen, Low's variety (*S.-L. heatonensis* × *Cattleya Mossiae*), from Messrs. STUART LOW AND CO., Jarvisbrook A very distinct and bright flower with sepals and petals vinous purple, and ruby-crimson lip.

GROUPS.

G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. Page), was awarded a Silver-gilt Lindley Medal for a magnificent group of Cypripediums in which his famous hybrids of C. Christopher were prominent. Specially noteworthy in this grand collection, in which all the specimens were superbly grown, were C. Mrs. Eley, C. H. J. Elwes, C. Memoria F. M. Ogilvie and C. W. H. Page. Fine specimens of the white Odontoglossum Pescatorei were arranged at the back of the exhibit.

Messrs. SANDERS, St Albans, received a Silver Flora Medal for an effective group, pretty novelties in which were Rolfeara Charm (B.-C. Mrs. J. Leemann × S.-C. Thwaitesii), a truly charming, blush-pink flower with Primrose-yellow disc; Cypripedium Rosalind (Niobe × Reginald Young), a perfect flower of the Niobe class, but more heavily marked, and C. Cyclopian (Cyclops × Leeanum Gratrixiæ), a good, distinct flower. Choice hybrid Cattleyas and Laelio-Cattleyas were also included in the group as well as a selection of species.

Mr. HARRY DIXON, Spencer Park Nurseries, Wandsworth Common, was awarded a Silver Banksian Medal for a group of the favourite yellow and white Cypripedium insigne Sanderæ, with several massive hybrids.

Messrs. FLORY AND BLACK, Slough, staged a group of exceptionally fine hybrids, in the centre of which was the very massive and finely-marked Cypripedium Maisie with a large dorsal sepal heavily blotched with dark claret-red, the petals and lip tinged with reddish purple. Other varieties of the same cross were also exhibited, but were not so showy.

OTHER EXHIBITS.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood) showed Angraecum distichum, Gomeza Barkeri and other species.

Sir HORACE MONRO, Woodland, Binfield, Bath, sent two Cypripediums imported from India as C. insigne Maulei, which was the correct name of one. The other was near to C. insigne Bohnhoffianum.

Messrs. STUART LOW AND CO., sent Cattleya Syros, Low's variety (Enid × labiata), a very large rosy-mauve flower, with a broad, purple-lip and white margin.

Messrs. ARMSTRONG AND BROWN, sent the new Cypripedium Luna (Desdemona x Mrs. Carey Batten) a pretty and well-formed flower.

Floral Committee

Present: Messrs. H. B. May (in the chair), W. J. Bean, E. A. Bowles, G. Reuthe, G. Harrow, J. F. McLeod, C. R. Fielder, H. J. Jones, T. Hay, Gerald Loder, W. Howe, Hugh Dickson, G. W. Leak, D. B. Crane, Andrew Ireland, H. V. Warrender, W. B. Gingell, Reginald Cory, W. G. Baker, Clarence Elliott, W. B. Cranfield and R. C. Notcutt.

AWARD OF MERIT.

Chrysanthemum Brightness.—A pleasing, small flowered Japanese variety of a deep but rather hard tone of purplish pink. It should be useful for late flowering and for cultivation in spray form. It is of interest to observe that this variety failed to obtain recognition at the hands of the National Chrysanthemum Society's Floral Committee on the previous day. Shown by Mr. H. W. THORP, Durrington, Worthing.

GROUPS.

Carnations presented a very bright and attractive appearance. Messrs. STUART LOW AND CO., arranged an especially meritorious group, which include several vases of the rich crimson Sir Mackay Edgar, while other sorts of similar bright colouring were British Triumph, Red Ensign, Reginald Cory and Lady Iverforth. Adjoining the Carnations they displayed floriferous plants of Acacia platyptera and Erica melanthera (Silver Flora Medal).

In a graceful stand Messrs. ALLWOOD BROS. continued their illustrations of the long-flowering season that is enjoyed by their Dianthus Allwoodii in many charming varieties. Amongst their perpetual-flowering Carnations were vases of Edward Allwood, of brilliant colour, Wivelsfield Claret, and Topsy, while the hybrid Malmaison, Mrs. C. F. Raphel, provided delicious fragrance and bright colour. (Silver Banksian Medal.) White flowered Carnations were prominently displayed by Mr. C. ENGELMANN. The chief varieties were White Wonder, White Enchantress, White Supreme, and Crystal White. Besides these there were many vases of other sorts, notably the 1924 variety, Donald, of bright crimson colour, and Topsy (Silver Banksian Medal).

While Chrysanthemums were not so numerous as at recent meetings, these autumn flowers was well represented. Messrs. KEITH LUXFORD AND CO. had some highly desirable Japanese varieties of exhibition size, as well as other types. The Japanese sorts of decorative size included Teresa and Kathleen May, of considerable value. Thora, a mauve coloured variety, was very attractive, as also were such singles as Merstham Jewel, Flora and Robert Collins. Two large vases of Pompons attracted considerabe attention. Mary Pickford white; Yellow Snowdrop, Julie Lagrave, crimson-maroon, and Francis Hutchinson, amaranth, are the names of a few of the dainty varieties. (Silver Flora Medal.)

Messrs. SCOTT AND WICKHAM staged several vases of splendidly grown blooms of Golden Butterfly. These were of rich colour, good size and borne on long stout stems (Bronze Banksian Medal). Chrysanthemums were associated with miniature gardens by Mr. FRED. G. WOOD, and with small bushes of various Conifers and Pieris floribunda by Messrs. BAKERS, LTD.

Just inside the entrance, Messrs. SUTTON AND SONS has a very attractive display of Chrysanthemums grown from seed sown this year. The flowers were mostly singles of medium size, and they illustrated a great variety of colours, besides being very free flowering. (Silver Banksian Medal.)

On a floor space, Messrs. L. R. RUSSELL, Ltd., displayed an attractive collection of hardy shrubs of value for their foliage. Ivies in standard and bush form, standard Euonymus and Lavender, well berried Skimmias, Pittosporum Silver Queen, and Corokeas were the principal shrubs shown. (Silver Banksian Medal.)

The Orpington Nurseries Co. set up a considerable variety of compact little Conifers, of value for planting in the rock garden, and also displayed healthy examples of Skimmia japonica and Berberis dulcis nana (Silver Banksian Medal). The Misses HOPKINS had an exhibit of alpine and rock garden plants. Mr. JOHN KLINKERT again displayed well grown topiary specimens and Mr. S. SMITH showed a number of miniature gardens of varied succulent plants (Bronze Banksian Medal).

A further selection of dried flowers and grasses was exhibited by the FRENCH INTENSIVE GARDENS COMPANY, the grasses included graceful bunches of Hordeum jubatum, Anthoxanthum gracile, Eragrostis elegans, E. nebulosa, Lagurus ovatus and Agrostis pulchella. Helichrysums, Statices, Acroclinums and Gomphrena globosa were the principal flowering plants used (Bronze Banksian Medal).

Several exhibits of garden sundries added variety to the meeting. Major WOOD showed his Fruit Tree Protector. Mr J. HAWS set up watering cans of various sizes. Messrs. HARDY LTD. displayed their rustless spades. The RADIUM FERTILIZER Co. and the CROSS BONE MANURE Co. had samples of their preparations.

Paintings of garden scenes and flowers were shown by Miss WINIFRED WALKER, Miss G. DORRIEN-SMITH, Miss ADIE, Miss ELLEN WARRINGTON, Miss M. AUMONNIER, Miss ALICE WILKINSON, Miss EDITH FISHER, Miss M. KILPATRICK, Miss MAUDE ANGELL, Miss EVA FRANCIS, and Mrs. EDITH A. ANDREWS, while Mr. C. CANE showed garden photographs and plans.

Fruit and Vegetable Committee.

Present: Messrs. J. Cheal (in the Chair), Geo. F. Tinley, W. J. Jefferies, S. B. Dicks, W. F. Giles, A. Bullock, H. Markham, W. H. Divers, W. Poupart, E. Neal, E. Beckett, A. Metcalfe, W. G. Lobjoit, A. E. Smith, J. G. Weston, T. Pateman, G. Reynolds, F. Jordan and A. Rawes.

The only exhibit in this section was a collection of Apples staged by Messrs G. BUNYARD AND CO. LTD., to show the best varieties in season. The fruits were all splendid specimens; the varieties were Orleans Reinette, Hormead's Pearmain, Claygate Pearmain, Newton Wonder, Rival, Lane's Prince Albert, Belle de Boskoop, Lord Derby, Cox's Orange Pippin, Baumann's Red Winter Reinette, Bramley's Seedling and Allington Pippin.

TRIAL OF BRUSSELS SPROUTS.

THE following awards have been made to Brussels Sprouts by the Royal Horticultural Society after trial at Wisley.

AWARDS OF MERIT.

Solidity, sent by Messrs. WHEELER, Warminster; *One and All*, sent by Mr. F. C. HEINEMANN, Erfurt, Germany; *Darlington*, sent by Messrs. NUTTING AND SONS, LTD., 106, Southwark Street, London.

HIGHLY COMMENDED.

Standard, sent by Messrs. BARR AND SONS, 11, King Street, Covent Garden, London; Half Long Paris, sent by MESSRS. TOOGOOD AND SON, Southampton; Walton Dwarf No. 12, sent by Messrs. W. ROWLANDS AND CO., Childwell Nurseries, Liverpool; Walton Dwarf No. 2, sent by Messrs. W. ROWLAND AND CO.

COMMENDED.

Dwarf Selected, sent by Messrs. ZWAAN AND DE WILJES, Scheemda, Holland; Ideal, sent by Messrs. DICKSON, BROWN AND TAIT, 57, Cross Street, Manchester; Early Tall Improved, sent by Messrs. ZWAAN AND DE WILJES; Walton Dwarf No. 8, sent by Messrs. W. ROWLANDS AND CO.; Selected No. 1, sent by Messrs. G. COOPER, 125, Midland Road, Bedford; Selected No. 2, sent by Messrs. G. COOPER; Masterpiece, sent by Messrs. J. P. HARVEY, Kidderminster; Early Giant, sent by Mr. J. L. CLUCAS, Moor Street, Ormskirk.

NATIONAL CHRYSANTHEMUM.

THE Floral Committee of the National Chrysanthemum Society met at the Royal Horticultural Hall on the 10th inst., and considered the merits of no fewer than twelve novelties, two of which received awards.

FIRST-CLASS CERTIFICATES.

Bronze Age. (II. 1.B.).—A very useful, deep bronze-coloured Japanese variety of medium size and pleasing form, and apparently useful for the production of flowers in sprays. Shown by Mr. H. W. THORP, Worthing.

Mr. J. Barrell (V. 2.A.).—A particularly handsome, single variety of large size and fine substance. The florets are broad and of a brilliant chestnut-red colour, with yellow base. The flowers are carried on long, erect, stiff dark stems. Shown by Mr. T. STEVENSON, Cowley.

The Executive Committee of the Society met during the evening of the 10th inst., and arranged many matters in connection with the Society's activities during the coming year. The financial position of the Society appears to be quite sound, and the results of the exhibition in November last were very satisfactory. At the close of the routine business, Mr. T. Stevenson gave an address on "Bud Manipulation," and added greatly to the interest of his observations by a display of flowers showing the results of various methods of stopping and bud-taking.

The Annual Meeting of the Society will be held on Monday, February 4th, 1924.

ROYAL SCOTTISH ARBORICULTURAL.

ABERDEEN BRANCH.

The Annual General Meeting of the members of this branch was held in Aberdeen on Saturday, the 8th inst., Sir John R. Gladstone, Bt., of Fasque, Kincardineshire, presiding. Mr. George D. Massie, advocate, Aberdeen, secretary and treasurer of the branch, submitted his annual report, which showed that the branch had had a successful year, the membership being one hundred and four an increase of four over the previous year. The finances are satisfactory, there being a credit balance of £22 6s. 0d. The following office-bearers were elected:—President: Sir John R. Gladstone; Vice-Presidents: Mr. John Michie, M.V.O., Kincairn, Blairs; Mr. S. J. Gammell of Countesswells, Captain R. J. Nicol, of Ballogie, and Provost Donald Munro, Banchory. Mr. George D. Massie was unanimously re-elected secretary and treasurer.

A feature of the proceedings was the reading of an instructive paper by Mr. G. K. Fraser, M.A., B.Sc., of the Forestry Department of Aberdeen University, on "Silvicultural Practice in Relation to Soil," in which he pointed out that to the forester it was abundantly evident that the quality of his crop was influenced to a high degree not only by the condition of weather and of exposure to which the crop was subject, but also by the quality or type of soil upon which the crop was grown.

Owing to our climatic position, any soil which was left free of tall shrub or tree growth tended to become invaded by numerous plants which had the tendency to cause a distinct loss in the mineral fertility of the soil and a deterioration of quality by a gradual increase in sourness, and the final formation of Peat Moss or barren heath. The first crop after war felling was a magnificent growth of Foxgloves, which might be taken as indicative of a good quality of Spruce land; then in a year or two the areas were covered by soft meadow grasses; and now we have grassy heaths overrun by heather and moor grasses, rendering the land quite unsuited to the growth of Spruce; indeed, in a generation or two peat-cutting may be possible on these areas. This shows that all land from which trees had been felled should be replanted as soon as possible. When the forest was felled the increased action of the sun and weather caused a quicker decay of leaf-mould and hence supplemented the amount of food supply in the soil.

After dealing with the question of brushwood burning, in which he advised the burning of fairly large sizes of brush which could not be marketed, Mr. Fraser touched on soil improvement. The process of soil deterioration seemed to be due to a very considerable degree to the rapid drying of the surface of the soil by wind, or to the greater liability of the soil to weather variations in general. One of the effects of immediate planting was to reduce this danger to a minimum.

Obituary.

James Brown.—We regret to announce the death, at his residence, Hillhall, Aberlour, Banffshire, of Mr. James Brown, who was for over thirty years head forester to the Findlays of Aberlour. He was chosen for the post by the late Mr. J. R. Findlay of Aberlour, and leading proprietor of *The Scotsman* newspaper, and right well did he justify the choice. Possessed of very high qualifications, Mr. Brown was held in warm esteem by the present proprietor, Sir John R. Findlay, and his household. The funeral, which was largely attended, took place on Wednesday, the 5th inst., at Aberlour Churchyard. Mr. Brown, who was 59 years of age, is survived by a widow and grown-up family.

Dugald MacNeill.—Many gardeners will regret to learn of the death of Mr. Dugald MacNeill, aged 74 years, which occurred at Gargunnock Gardens on the 4th inst. Mr. MacNeill, who was a native of the Island of Colonsay, served his apprenticeship as a gardener in Killoran Gardens, Colonsay. During his career he was employed at Burnhead, Edinburgh, and in the nurseries of Messrs. R. B. Laird and Son. Subsequently, he became gardener at Yair, Selkirkshire, where he served for a period. After leaving Yair, he was appointed gardener and overseer to the late Colonel Stirling, at Gargunnock House, which position he retained for over forty years. He was an intimate friend of the late Mr. W. Thomson, of Tweed Vineyards, and from him he gained an excellent knowledge of vine culture. A keen judge of a good flower, fruit, or vegetable, his services were greatly appreciated by local horticultural societies. At the shows of the Stirling Chrysanthemum Society he was a prominent prize-winner, in all sections. He was a man of quiet disposition, ever ready to help members of his craft, and did all he could to assist the struggling young gardener along the road to success. He leaves three sons and one daughter to mourn his loss.

TRADE NOTES.

MR. R. J. WALLIS has taken over the nurseries formerly belonging to the Scott family at Merriott, near Crewkerne, Somersetshire. Mr. Wallis is well known to many of our readers, for he was at one time Secretary to the Floral Committee of the Royal Horticultural Society and assistant in the Wisley Gardens; he was also for some considerable time in the employ of Messrs. R. W. Wallace and Co. in their old nurseries at Colchester. The nurseries at Merriott specialise in fruit trees and Roses, and also include large stocks of Conifers and ornamental trees. In addition, Mr. Wallis is cultivating the finest types of hardy plants, including herbaceous flowers and Alpines, and is also undertaking the designing and planting of gardens for clients.

HERR HEINRICH KASTNER, the head gardener, or "Garteninspector," in the well known Berlin nursery firm of M. L. Späth, has just celebrated his seventieth birthday. He has been manager of the despatching department and of the Arboretum for forty-four years, and still has the oversight of these departments. He is quite hale and hearty, and his birthday was celebrated by his friends and employers in great style.

THE WEATHER.

THE WEATHER IN NOVEMBER.

THIS was one of the sunniest Novembers on record locally; but yet, in great part, exceedingly wet. After the first few days, it was also very cold. The concluding ten days were mainly dry and calm, and were particularly cold. The mean temperature of the complete month was 39.8°, or 3.5° below the fifty years' average. Frost occurred in the open on no fewer than 18 nights, and on 12 of these in the shade also; but no especially low readings were recorded. The duration of sunshine amounted to 75 hours, the normal being exceeded by 20 hours. Rain fell on 19 days, or two more than usual; and the total was so much as 4.86 inches, or 1.78 inch above the average. In five days, from the 12th to the 16th inclusive, more than the whole month's normal rainfall was precipitated. The underground water level rose considerably. Hail fell on no fewer than 10 days, and thunder occurred on three days; each of these is the largest number for November in the local records. There was ice on the lake in Hesketh Park on 11 days, and by the 30th it had attained a thickness of 1.8 inch. Dense fog was confined to the morning of the 30th, the usual south-easterly winds of the end of autumn being replaced by much clearer northerly and north-easterly ones. Gales were experienced on six days. During a curiously prolonged and violent squall, shortly after noon on the 15th, several gusts were at the rate of 85 miles per hour. *Joseph Baxendell, Borough Meteorologist, The Fernley Observatory, Southport.*

THE WEATHER IN SCOTLAND.

"CHILL NOVEMBER" continued to maintain its reputation, a considerable drop in the temperature occurring from the previous month, snow, and snow lying, being recorded in the last three days. Bright sunshine totalled 79.6 hours, giving a daily average of 2.65 hours and a percentage of 30. There were only four absolutely sunless days. Rain was collected to the extent of 2.20 inches, being slightly under the normal. There were 11 official rain days, the 15th yielding the most, viz., .65 of an inch, 10 days of precipitation and 9 days on which no rain fell. In the screen, the highest maximum temperature occurred on the 2nd, viz., 54°, the lowest maximum of 36° on the 23rd, 27th and 29th respectively. The highest minimum 45° occurred on the 12th and the lowest 26° on the 15th. On the grass the 12th also gave the highest reading of 44°, while the lowest, of 22°, was on the 25th. There were 14 days of ground frost. The soil temperature, at a foot deep, dropped from 46° at the beginning to 35° at the close of the month. Barometric pressure was greatest on the 10th, viz., 30.405 inches, and lowest on the 14th, 28.867 inches, the 12th to the 18th being a period of comparatively low pressure. The sky was frequently obscured by haze, mist occurring on the 5th and a fog of extreme density on the 27th. Wind velocity was seldom great; only on the evening of the 15th did it assume gale force. Lunar coronas were observed on the evening of the 19th and morning of 30th, also a rainbow at 2.35 p.m. on the 20th.—*John Davidson, Director of Studies, Training College Gardens, Mayfield, Dundee.*

ANSWERS TO CORRESPONDENTS.

CYCLAMEN DISEASED: *E. M.* Although we could find no mites or red spider on the leaves, the colouring of the underside of the foliage suggests that there have been attacks of one or both of these pests. As prevention is better than cure, it will be desirable to watch for an early attack or prevent one by frequently dusting the undersides of the leaves with tobacco powder.

FUNGUS IN A PEACH BORDER: *G. A.* The fungus growing as a white, fluffy mycelium in the two samples of soil sent is one of the "Fungi Imperfecta" (Rhinotrichum Thwaitsii). So far as we are aware this fungus causes no damage. It is not infrequent in woods, particularly where the soil is of a heavy, clayey nature.

GRUBS AMONG CYCLAMEN ROOTS: *J. P.* The Grubs which have eaten the roots of your Cyclamen are the larvae of Otiorrhynchus sulcatus, the Vine weevil, which are often imported in leaf mould. If your plants have suffered very much, shake the soil from the roots and repot them in a sterilised compost. In every case it is desirable to sterilise leaf mould before it is used, as it frequently contains destructive pests.

HOGG'S "FRUIT MANUAL": *T. T.* You may possibly obtain a copy of Hogg's *Fruit Manual* from one of the firms who deal in second-hand books, or you might advertise for a copy, as no doubt there are some gardeners who would be willing to dispose of one. A useful book dealing with Apples and Pears is Bunyard's *Handbook of Fruits*, which may be obtained from our Publishing Department, price 8/- post free.

NAMES OF FRUITS: *W. W.* 1, Adams's Pearmain; 2, probably Gravenstein; 3, Warner's King.

NAMES OF PLANTS: *W. F.* 1, Thuya dolabrata var. variegata; 2, Cupressus pisifera var. squarrosa; 3, Juniperus communis var. fastigiata; 4, Cupressus pisifera var. plumosa; 5, C. Lawsoniana var. erecta viridis; 6, C. nootkatensis; 7, Picea Omorica; 8, Abies firma; 9, Cedrus Deodara; 10, Cupressus obtusa var. gracilis aurea; 11, C. obtusa var. gracilis; 12, Cupressus Lawsoniana; 13, Viburnum rhytidophyllum; 14, missing; 15, Quercus cuspidata; 16, Quercus glandulifera; 17, Cassinia fulvida; 18, Quercus lanuginosa. *F. D. H.* Pittosporum undulatum.

PLANTING ON THE SEA FRONT: *J. J* The Wych Elm will prove much more satisfactory than the Canadian Poplar as an avenue tree near the sea. The Sycamore, White Poplar, Willow, Ash, and Maritime Pine are suitable subjects as wind screens for the protection of better class trees on the sea coast. Always provided that the climate is suitable the following shrubs do well in the vicinity of the sea:—Guelder Rose, Escallonia, Fuchsia Riccartonii, Laurustinus, Gorse, various species of Veronica, Weigela Buckthorn, Olearia Haastii, and Tamarix.,

PROPAGATING BEGONIA MRS. PETERSEN: *J. N.* This variety of Begonia may be propagated by means of leaves at this time, but November is the best month for inserting the leaves, as this slow growing variety needs a long season of growth. The leaves are best put in without cutting off the leaf-stalk; the blade of the leaf can thus be kept clear of the soil, and damping will be largely obviated. They are best dibbled into a bed of cocoa-nut fibre and sand in an open propagating bed; or peat-moss litter and sand may be used in place of cocoa-nut fibre. Cuttings inserted during November and December give the best results, and by this method of propagation you should experience no difficulty in producing good plants in 48-sized pots. If large specimens are required the plants should be grown on for the second year.

REMARKS.—Supplies from home growers have been gradually lessening during the past week. Roses are very scarce, and those sent have been cleared very early. Richardias (Arums) are still very limited in numbers and, like Liliums, realise a high price, the market being quickly cleared of these subjects. The value of Carnations has fallen owing to a better supply. Good Chrysanthemums are dearer both blooms and "sprays"; the best sorts are Heston White, Winter Cheer, Wilcox, Negoya, and Baldock Crimson. The best white disbudded blooms are Autocrat and Favourite; coloured sorts include Winter Cheer, Negoya, Tuxedo, December Gold, W. H. Lincoln, and Hortus Toulousainus (bronze). A few large Hyacinths, on bulbs, will be on sale this week. Tulips are also shortly expected to make their first appearance in the market this season. Supplies of flowers from the continent have been lessening and are getting dearer, owing to the bad weather in France. There is likely to be a further shortage with a general rise in prices for some days to come, especially for Narcissus. Violets are now arriving in excellent condition, and with Parma Violets more plentiful their prices are again normal. Roses are also arriving in a fairly good condition; the varieties consist of Ulrich Brunner, Frau Karl Druschki, and Safrano. Better consignments of white Lilac are being received from Holland about three times weekly. A few sprays of mauve Lilac were on sale last week.

REMARKS.—In some sections there is a maintenance of the recent small improvement in business, but generally the trade is dull. There is a fairly steady inquiry for Apples in barrels and cases, but the stocks on hand are large. Larger quantities of English Apples have been available lately and prices are not so firm, even for large cookers. Cox's Orange Pippin, however, is an exception, and the demand is sufficient to maintain prices at their former level. Grapes are a strong line just now, and both English and Belgium Grapes are selling freely. Pineapples for the Christmas trade are also popular, the latest consignment selling readily. Oranges are not a good trade; the bulk of the fruits from Spain are immature and lack sweetness. Guernsey Beans show a better inquiry with an advance in price. Forced Asparagus, on the contrary, is a drug on the market, and saleable only a very low figures. A few forced Potatos have sold readily, but, for the most part, the tubers are not good, and not the sort wanted by the trade. Beans from Madeira are plentiful and cheap and have been arriving in good condition; Mushrooms are a good trade and supplies moderate. A few well-coloured new crop English Tomatos are selling at satisfactory prices, but other sorts are almost unsaleable. Tomatos from the Canary Islands are only in moderate demand; the quantities on hand are heavy. The few Cucumbers available are selling at high prices. Seakale is in short supply and prices are firm. Green vegetables are steady in price. There is an upward tendency in the Potato trade.

GARDENING APPOINTMENTS.

Mr. A. Aylett for the past three years Gardener to H.I.H. Prince Napoleon at Farnborough Hill, Farnborough, Hampshire, as Gardener to H.I.H. at the Chateau de Rouchinne, Par., Assesse, Provence de Namur, Belgium. (Thanks for 2s. 6d. for R.G.O.F. Box)—EDS.

Mr. A. W. Elliott, for the past nine-and-a-half years Gardener to the late W. L. NICKELS, Esq., Chenetrie, Noctorum, Birkenhead, as Gardener to the same gentleman at Hallsannery, Bideford, North Devon. (Thanks for 2s. 6d. for R.G.O.F. Box—EDS.)

Mr. T. A. Hooker, for eight years Gardener to Sir BERKELEY MOYNIHAN, Bt., Carr Manor, Meanwood, Leeds, as Gardener to EDGAR L. GAUNT, Esq., Hawksworth Hall, Guiseley, Near Leeds.

Mr. William T. Parsons, for the past seven years and eight months Gardener to the late Captain E. H. SAWBRIDGE, J.P., Denford House, Hungerford, Berkshire, as Gardener to Sir FREDERICK H. W. CARDEN, Bt., Stargroves, Newbury, Berkshire (Thanks for 2s. 6d. for R.G.O.F. Box)—EDS.)

Mr. F. A. Reynolds, for four years Gardener to H. O. HOSEASON, Esq., Letcombe Manor, Wantage, Berkshire, as Gardener to A. E. MALLANDAIN, Esq., Tankerton Towers, Whitstable, Kent. (Thanks for 2s. for R.G.O.F. Box—EDS.)

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.6.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, December 19. 10 a.m.: Bar, 30.3; temp. 41°. Weather—Bright.

Plum Stocks.

THE perfect stock from the point of view of the gardener does not exist. Among the qualities which the ideal Plum stock should possess are a constant habit, reasonable ease of propagation, a good anchoring, non-suckering root system, a dwarfing effect on the scion, so that growth is restricted, a readiness of union with the scion, early bearing, and the power of aiding the scion to resist or recover from Silver-leaf Disease. In view of this formidable catalogue of virtues required of Plum stocks, it is not perhaps surprising that the search for the possessor thereof, although it has engaged the skilled energies of Mr. Hatton and his colleagues at the East Malling Research Station, has not yet proved wholly successful. Nevertheless, as the most recently published results* of the East Malling investigations show, great progress has been made in ascertaining the properties of the many Plum stocks in common use. The need for this preliminary investigation is the more important in that from their habit of suckering freely certain stocks have come into common use, in large measure regardless of any consideration other than that of the ease with which they may be propagated. It is no doubt for this reason that nearly every Plum growing district has its local Plum, the suckers of which are used largely in that district as stock—Bush Plum and Farleigh Damson in Kent, Pershore in Worcestershire, Blaisdon in Gloucestershire, the Gage in Cambridge, and the Drooper in Warwickshire. On the other hand, nurserymen generally select their stocks from the Brussels, Brompton, common Plum, various Mussels, Myrobalans, St. Juliens and Black Dumas, and consequently these stocks are widely distributed among the orchards of the country. One fact which emerged from the East Malling investigations is that—as might be expected — seedling stocks, *e.g.*, of Myrobalan and St. Julien show considerable variability and hence it is necessary for nurserymen to make careful selection if uniformity is to be achieved, and having selected the right stock to keep it true by propagating it vegetatively and not by seed. Among the stocks which are most easily raised are the Brussels and common Plum from layers; the Mussels for layers and root cuttings; Pershore and Brompton are, on the contrary, rather shy of rooting. The trials at East Malling, although they must be continued for many years yet before they admit of certain conclusions, already indicate that some stocks make better "mothers" than others—that is, "take" the buds and grafts of most varieties and enable the scions to form good maiden trees. Such are Pershore, Myrobalan and Brompton. These stocks would therefore seem safe for general use. Other stocks are not so accommodating and do not mate readily with certain varieties of Plum and Damson. In this group are included common Plum, Brussels and Broad-leaved Mussel. In illustration, the result of budding Czar on some of these varieties may be cited. With Myrobalan and Brompton about ninety per cent. of the buds of the Czar put on them "took"; nearly eighty per cent. took on Pershore, but on Brussels and Common Plum more than three-quarters of the buds of Czar put on them failed. Although no dwarfing stock has as yet been discovered, some, *e.g.*, Brussels and Common Plum, have a slightly restricting effect. Vigour, if required, may be had by using Myrobalan, Brompton, and Pershore; but in our experience, Plums generally suffer from excess of vigour and a more dwarfing stock than may yet be introduced remains greatly to be desired. On Pershore or Common Mussel and some St. Julien, varieties like Victoria blossom at an early age and more freely than on other stocks and, hence, come into thrifty bearing earlier. Pershore and some St. Julien stocks accelerate the time of flowering—a very doubtful advantage, and some, such as Brompton, Myrobalan and certain St. Juliens, provide a firmer anchorage than do other stocks. The bad suckerers are Brussels, common Mussel and common Plum: Brompton, some Myrobalan forms and Pershore are more free from this defect. Unfortunately, the results obtained by Mr. Brooks and the indications noted at East Malling, hold out little hope that choice of stock will help to reduce risk of Silver-leaf Disease. There is the possibility, however, that one type of Myrobalan and common Mussel which show a measure of resistance to Silver-leaf Disease may prove of value in this respect. Although work of the kind which is being prosecuted at East Malling is, of necessity, long in leading to conclusions, all horticulturists who follow it recognise that this work is on sound and sure lines. In consequence, even the interim reports which are issued from the Station have great practical value. The progressive nurseryman cognisant of the futility of rule of thumb methods can ponder the results and draw his conclusions as to whether on the whole the stocks he is accustomed to use are the best available, or whether he should not begin to co-operate with East Malling by trying other stocks side by side with those which he is accustomed to use and the virtues and defects of which he knows.

* "Some Notes on Stocks for Plums." By R. G. Hatton, M.A. Reprinted from the *Journal of the Kent Farmers Union*, November, 1923. Price 2d., plus postage.

"Gardeners' Chronicle" Almanack for 1924.—We shall publish in our issue of January 12 a "Gardeners' Chronicle" Almanack for the year 1924. In order to make it as useful as possible for reference we shall be obliged if Secretaries of Horticultural, Botanical, and Allied Societies, or any of our correspondents WILL SEND US IMMEDIATE INFORMATION OF ALL FIXTURES FOR THE ENSUING YEAR.

A Horticultural Visitor from America.—On the 8th inst. Mr. Nathaniel Ireland sailed from New York, on the White Star Liner, Baltic, for Liverpool. He is on an extended visit to Europe and will not return for at least two months. Mr. N. Ireland is a brother of Mr. Andrew Ireland, of Marks Tey, Essex, and he is in charge of the Charles M. Schwab estate at Loretto. He is visiting Europe on behalf of Mr. Schwab and after inspecting the leading horticultural establishments in England and Scotland, he will proceed to France and Italy for the purpose of studying many of the famous gardens in those countries.

Catalpas.—Catalpa bignonioides, often sent out by nurserymen under its synonymous name of C. syringaefolia, is still the species most generally cultivated in this country. Yet, as pointed out in the *Bulletin of Popular Information* (No. 12), published by the Arnold Aboretum, another American Catalpa, C. speciosa, is superior to it. Indeed, the writer in the *Bulletin* claims for this species that it is the largest, fastest growing, the hardiest and the handsomest of all Catalpa trees. Whereas the former species was introduced into England from South Carolina in the early part of the eighteenth century, C. speciosa, the home of which is along the Ohio and Mississippi rivers, has only been in cultivation for about fifty years. In its natural home this species reaches a height of 120 feet and forms a trunk four and a half feet in diameter. Elsewhere it fails to reach these dimensions, yet in eastern Massachusetts trees not more than fifty years old have attained a height of forty feet and have been flowering and fruiting for many years. A Chinese species, C. ovata, though of little value as an ornamental tree, is hardier than the American species and has yielded the hybrid C. hybrida, C. Teasii or Teas' hybrid Catalpa, as the result of a natural cross with C. bignonioides. Wilson's two Chinese species, C. Duclouxii and C. Fargesii, though still living in the Arboretum, gave but little promise of becoming useful garden trees.

Southport Floral Fete in 1924.—At a meeting held on the 11th inst., the Southport Town Council adopted the recommendation of its Parks and Finance Committees that a three days' Floral Fete be held in Southport on August 27, 28 and 29, 1924.

Mr. C. G. Engelmann's Success at Cambridge.—We are very pleased to announce that Mr C. George Engelmann, eldest son of Mr. C. Engelmann, of Saffron Walden, has obtained his B.A. Degree in Horticulture at Cambridge. He is the fourth to obtain this degree at Cambridge, and the youngest to obtain it during the present term. As he is only nineteen years of age, this early success marks him as a particularly promising student in the higher branches of the horticultural industry.

"Fruit Grower" Directory and Handbook, 1924.—The *Fruit Grower Directory and Handbook* for 1924 contains 468 pages filled with information of interest to fruit growers, and especially those who grow for market. For a work of this nature there are exceedingly few advertisements, although these in themselves are often of value, especially to traders who may require to give an estimate at short notice. The bulk of the book is devoted to a list of firms, arranged in alphabetical order, comprising fruit growers, fruit importers, seed growers, salesmen, florists, sundries' merchants, &c., and this is followed by a classified section in which dealers in certain goods may be easily referred to. Thus the first page includes agents, anthracite merchants, associations, federations and societies, auctioneers and estate agents, Bamboo merchants, manufacturers of banding materials, and so on. In this section are lists of flower growers, and fruit growers, the respective lists filling several pages, and there are also long lists of fruit and vegetable growers, glass-house nurserymen, market gardeners, and others connected with fruit growing and allied industries. There are also useful lists of commission agents, fruit growers, nurserymen, &c., in a Colonial section, which embraces Australia, New Zealand, India, Canada, and South Africa. A Continental section contains similar lists of traders in the industry in Europe, whilst a foreign section embraces the United States of America, South America, and Japan. Much statistical matter is given in the first hundred pages, all useful information, not only to fruit growers, but to cultivators generally. The names of the best kinds of fruits, plants, and flowers for market are given, with short descriptions of each, showing which are the most popular sorts for market purposes. A cultural diary gives the fruit-grower's calendar of work during the various months of the year. Railway rates and regulations are dealt with very exhaustively, and there are chapters on notifiable diseases and pests, and various Acts, such as the Seeds Act, 1920; the Sale of Horticultural Poisons; the composition of insecticides and fungicides, &c. An article on "Legal Points affecting the Horticultural Trade," gives much useful information in cases that have been dealt with in the Courts. Portraits and short biographies of prominent growers are given in the section on "Prominent men in Horticulture." This directory is well printed in bold type, and has a very attractive binding in stiff linen covers; it is published by Messrs. Benn Bros., 8, Bouverie Street, E.C, price 10s.

R.H.S. Gardeners' Pocket Diary. — The appearance of the *R.H.S. Gardeners' Pocket Diary* for 1924 is opportune as the present year is drawing rapidly to its close and the careful gardener will be ordering his diaries for the coming year. The big foolscap diaries that do duty in the potting shed and gardener's office are very useful for recording practical work done, and for making notes of duties to be performed, but every gardener, amateur or professional, needs a small, handy, and smart-looking pocket diary in which to record engagements and observations made at exhibitions, meetings and visits to gardens, and it is for this latter purpose that the R.H.S. Diary is so useful and handy. The useful features of the previous twelve editions are retained in the new and thirteenth issue, and while the information giving is necessarily incomplete, owing to the limitations imposed by the size of the diary, it is always open to a gardener to make suggestions for improvement, as these will be welcomed by Mr. W. R. Dykes, the Secretary of the R.H.S and Editor of the Diary, and "carefully considered and adopted, if possible." Copies may be obtained from our Publishing Department, for 2s. 3d. post free.

Memorial to the late Professor Trail.—Warm tributes were paid to the work and worth of the late Professor James W. H. Trail, F.R.S. (who for forty-two years occupied the Chair of Botany at Aberdeen University), on the afternoon of Friday the 7th inst. The occasion was the unveiling of a memorial tablet in the new Botany Department of the University at the Cruickshank Botanic Gardens, Old Aberdeen. Sir David Prain, F.R.S., formerly Director of the Royal Botanic Gardens, Kew, a graduate of Aberdeen University, and a member of Professor Trail's first class in 1877, performed the unveiling ceremony. Sir George Adam Smith, Principal of Aberdeen University, presided over a large audience, including Mrs. Trail, Sir Francis Grant Ogilvie, C.B., of the Carnegie Trust; Professor W. G. Craib, who now fills

MEMORIAL TABLET TO THE LATE PROFESSOR TRAIL IN THE BOTANY DEPARTMENT OF THE ABERDEEN UNIVERSITY.

Professor Trail's chair; Professor J. Arthur Thomson, of the Chair of Natural History, Aberdeen; and Dr. Macgregor Skene, Lecturer in Plant Physiology, who acted as secretary to the Memorial Committee. The bronze tablet is mounted on a slate slab with a portrait plaque of Dr. Trail in the centre. In addition to the tablet the memorial includes a *Professor Trail Memorial Volume*. This volume contains an interesting biographical notice of Professor J. W. H. Trail, by Mrs. Trail; a bibliography of Professor Trail's works; and "The Flora of the City of Aberdeen." Professor Craib, in introducing Sir David Prain, said it was appropriate that Sir David should take a prominent part in their proceedings that afternoon, for he was a member of Professor Trail's first class, and after graduating had maintained his friendship with the Professor. Sir David Prain, after unveiling the tablet, said the audience would notice that the portrait was flanked by two Brazilian Palms. They commemorated the fact that one of the earliest, and at the same time one of the most important, contributions that Professor Trail made to botany was in connection with the Palms of the Amazon. The wreath that surrounded the portrait was of Oak leaves and acorns and galls, which were so typical of Professor Trail. Below the inscription, in two decorative panels, were two symbolic and yet real references to his work. On one side was the dragon fly, representing Professor Trail's work on insects, and the water spider, which was the subject of one of his earliest papers. On the other side was the Bladderwort, which was the subject of one of his latest papers. Below that there was the following inscription: "In memory of J. W. H. Trail, M.D., F.R.S. Born Birsay, Orkney, 1851. Traveller on the Amazon, 1873-5. Professor of Botany in Aberdeen University from 1877 till his death in 1919. Fellow of the Royal Society. He knew and loved the realm of living Nature, and inspired successive generations of students with his desire for deeper knowledge." Those beautiful words, said Sir David, expressed the aptitude of Professor Trail as a teacher, but as a friend of forty-two years standing he desired to say that his high integrity, the staunchness of his friendship, and his zeal for intellectual progress in all branches of knowledge were equal to what he did in and for natural history. Sir David then asked Principal Sir George Adam Smith to take over the custody of the memorial and the manuscript of the memorial volume. Principal Sir George Adam Smith accepted custody of the memorial, and promised that the University would cherish it with the reverence and affection that were due to Professor Trail's great memory. There never was a more loyal son of that Alma Mater than Dr. Trail, nor a servant of the University who, as teacher, served her more constantly than he did. He worthily earned the most enviable reputation that a teacher could aim at in having claimed so large a number of those who rose to high positions in the world of botanical teaching as teachers themselves. His colleagues would agree with him that there was no one who took a wider, a more impartial, a more liberal, and a more zealous interest in the progress of Aberdeen University than Professor Trail. To know him was not easy at first, but when one did get to know him one formed the very highest opinion of the purity, honesty, and unselfishness of his character. Another reason for remembering Dr. Trail was that he was almost the last link between the new order of things at the University and the old order that had passed away for ever. One had but to read the biographical sketch which was prefaced to the memorial volume to see what progress the University of Aberdeen had made since Dr. Trail left it as a student and during the forty-two years he served it as a Professor of Botany.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Caper Plant at Malta.* I observed the Caper bush growing in great abundance out of the crevices in the walls and ramparts of the island of Malta, where I spent two days in the end of June last. It was in full bloom at that time, and was really a handsome object; the long, white stamens tinged with purple contrasted finely with the clear green foliage. Some friends who were wandering about over the island with me sightseeing, fell into the common error regarding the Capers of commerce, and stoutly argued that it was the seed of the plant which we eat at our tables; nor could I convince them to the contrary until I procured a branch with some unexpanded flower buds upon it, and showed that these were what were gathered for use. *R. F. Gard. Chron., December* 16, 1848.

NOTICES OF BOOKS.

A TEXT-BOOK ON CONIFERS.

THE interest in Conifers is perennial and increases from year to year. New species and varieties continue to be discovered, enriching our parks and gardens with their added beauty. When the Kew *Handlist* appeared in 1903, the number of species in cultivation was 246, and of varieties 451; or some 700 sorts of Conifers in all. Since that date, striking novelties like Taiwania and Fokienia, and new kinds of Abies, Picea and Cupressus have been found in China and Formosa. The number of sports has also increased largely, as witness Mr. Hornibrook's recent book, which gives an account of no fewer than 460 dwarf varieties alone. How great must be the labour of giving a description of all the living species, which are now estimated at 380 in number, and of listing the crowd of sports and hybrids, which make the total sorts of Conifers more than 1000! This task, necessarily a compilation, has been accomplished by Messrs. Dallimore and Jackson in the handsome volume* before us.

The authors cater for the forester and gardener rather than for the botanist; and the non-introduced species are passed over with only a brief notice. The result is a practical handbook, specializing in the easy identification of the numerous species in cultivation by the use of artificial keys and plainly written descriptions. The student is greatly helped by the admirable series of 120 drawings by Miss G. Lister, which faithfully portray the branches, buds, leaves, cones and seeds of the more important species. In addition there are 32 plates, reproduced from photographs, which depict both forest scenes and individual trees. Some of these are very beautiful, and show the wonderful effect obtained by well-grown specimens. Those of rare species, like Abies amabilis, Abies magnifica, Fitzroya patagonica and Picea Breweriana, are of special interest. The genera and species, for the sake of easy reference, are arranged alphabetically under the two families of Taxaceae and Pinaceae, into which the Conifers are usually divided. This arrangement would have been more convenient if only one alphabetical series had been adopted.

Mr. Jackson is responsible for the accuracy of the botanical part of the work. The nomenclature of the species and varieties is satisfactory, as preference is given to familiar and long-established names. The economic side has been handled by Mr. Dallimore, who supplies up-to-date information concerning timbers and many other interesting forest products, such as resins, turpentines, oils, gums, tar, charcoal, lampblack, paper pulp, pine wool, manna, etc. The tests of the strengths of various woods, quoted from official reports at considerable length, are, however, of doubtful value, as they can only be applied in rare cases to commercial samples. Of much more use are the copious notes on cultivation, fungous diseases, and insect attacks which are given under the trees of silvicultural importance, like Larch, Pine, Spruce, and Douglas Fir.

The book is well printed and has a copious index, but the name of the genus should have headed every alternate page for the sake of easy reference. The localities given for the cultivation of tender species are too restricted, as the greater part of the maritime zone around Ireland and on the western Side of Wales and Scotland furnishes as congenial a home as Cornwall. Even in Sussex, on elevated sites above the frost zone, rare Conifers from Tasmania and New Zealand thrive amazingly. Pinus canariensis, stated on p. 378 to be quite unsuitable for the climate of the British Isles, grows vigorously in Wicklow. It is the best timber tree on limestone in the Riviera, and might well replace there the native Pinus halepensis, the economic value of which is very slight.

The proof-reading has been fairly good, but one or two curious mistakes have escaped notice. On p. 66, the first cuttings of the upright Irish Yew are said to have been sent to Lee and Kennedy's Nursery, London, in 1867. This year is merely the date of a memorandum giving the history of the tree, which was discovered a century earlier. (See *Irish Gardening*, Nov. 1908, p. 172). In 1780, cuttings from Florence Court were planted at Comber, Co. Down, which have grown into fine trees; and it was probably at the same time that the first cuttings were sent to London to spread from there all over the world. On p. 297 there is an error in the account of the remarkable creeping Larch, Larix pendula repens, two specimens being known, one at Henham Hall, Suffolk, supported on pillars and extending horizontally for over 100 feet, and another in the Cambridge Botanic Garden. The history of the Henham Larch is given by Loudon (*Gardeners' Magazine*, xv, p. 626, 1839, and xvii, p. 353, 1841). This extraordinary sport was a seedling of the hybrid Larix pendula, Salisbury. Other queer forms of similar origin were noted years ago in the St. Petersburg Botanic Garden, as mentioned in these columns, 9 Oct., 1915, p. 234. This is a striking example of mutations resulting from hybridity.

On the whole, Messrs. Dallimore and Jackson's handbook is remarkably accurate, and is worthy of a place in the library of every lover of Conifers. For the use of student, it supersedes works like Gordon's *Pinetum* and *Veitch's Manual*.

The authors are to be congratulated on producing a reliable work which meets a great need since the older books on Conifer are not only out-of-date but out-of-print. *A. Henry.*

* *Handbook of Coniferae, including Ginkgoaceae*; by W. Dallimore and A. Bruce Jackson, A.L.S. p.p. 570, with 120 drawings by Miss G. Lister, F.L.S., and 32 plates. Price 42*s.* net. E. Arnold & Co., 1923.

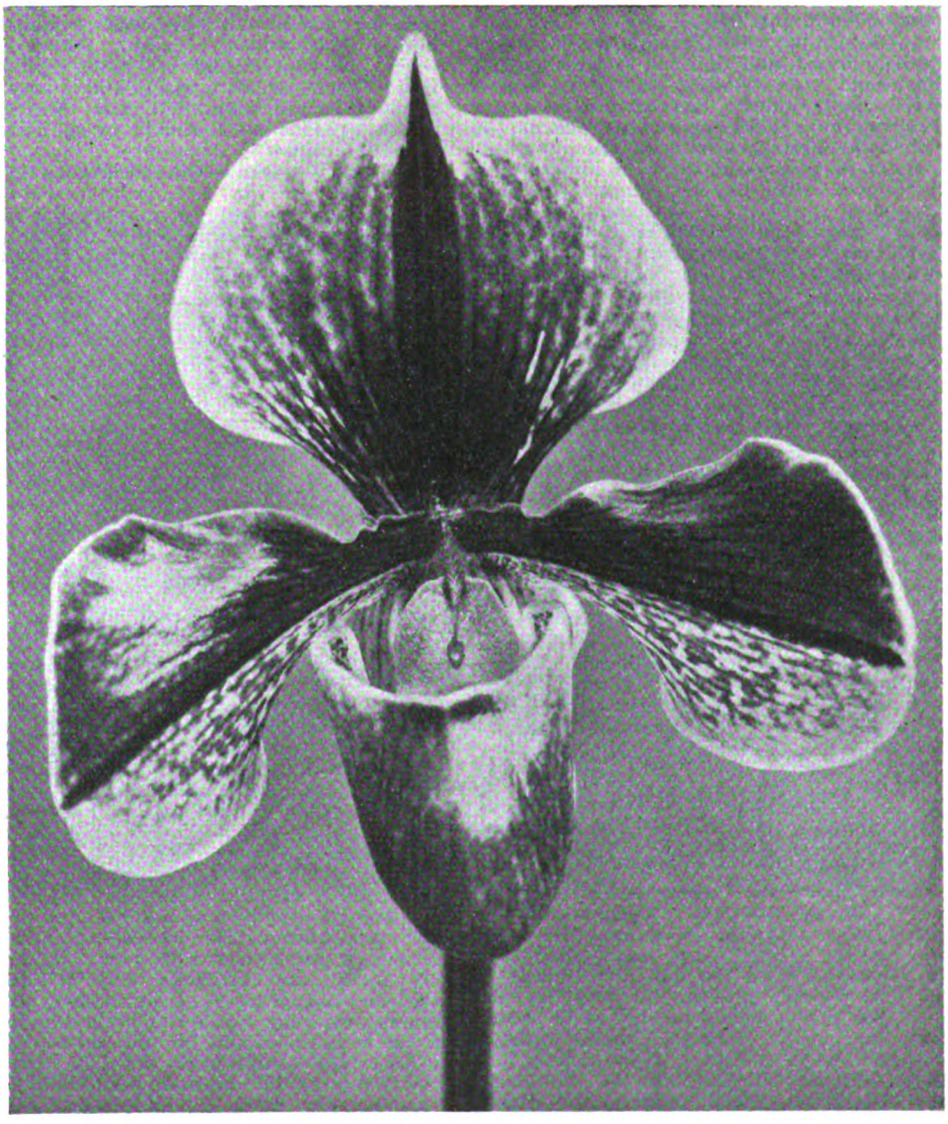

FIG. 128.—CYPRIPEDIUM PRINCE ALBERT, CHARDWAR VARIETY. R.H.S. FIRST-CLASS CERTIFICATE, DECEMBER 11 (SEE P. 356).

ORCHID NOTES AND GLEANINGS.

MILTONIODA HILDA.

A REMARKABLY pretty and distinct Miltonioda resulting from crossing Miltonia Roezlii and Cochlioda Noezliana has been flowering in Messrs. J. & A. McBean's nurseries at Cooksbridge, and flowers recently seen show that it is one of the most elegant of the Miltonia crosses. The plant has a finely branched spike densely set with pretty flowers, the sepals and petals of which are bright carmine-red and the proportionately large lip rose-pink. The flowers have a delicate fragrance derived from the M. Roezlii parent, a species which the present hybrid proves should be more extensively used in hybridising.

The Week's Work.

THE FLOWER GARDEN.

By C. TURNER, Gardener to EMILY, LADY AMPTHILL Ampthill Park, Ampthill, Bedfordshire.

Freshly Planted Subjects. — Hardy flowers, trees, and shrubs that have been planted recently should be examined after wind-storms and periods of frost, and if they are loose in the soil made firm at the roots. The re-firming of all shrubs and trees is best accomplished by treading with the foot or by the use of a large rammer, but small plants such as Carnations are best firmed with the hand to save breaking the foliage. An excellent plan in the case of freshly-planted Roses and other bush plants that may be top heavy is to tie one or two growths to a strong cane until the roots have a firm hold of the soil, when the supports may be removed. The practice entails rather more work than treading, but it ensures the plants being rigid and obviates any damage to the roots that might be caused through swaying to and fro.

Cuttings in Frames.—Stock raised from cuttings in frames is looking green and healthy. Take advantage of every favourable opportunity to admit air, as this will minimise risks from damping and keep the plants sturdy. Keep the plants clear of decaying leaves and lightly stir the soil occasionally. Choose mild days for watering.

Repairing Supports.—There are usually some supports that need to be made good, such as the stakes of standard Roses and those supporting wire enclosures. Such work should be attended to before the more busy days of Spring. Breaches in rustic arches or pergolas should also be made good, for this work may be better done now than when the climbers are in full growth and blossom. Wire arches used for the support of Roses and the like that have become loosened, may be held rigid by fixing a strong wire at one or both ends of the arch to an iron rod driven deeply into the ground.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Dendrobium.—The flower buds of many of the deciduous and semi-deciduous Dendrobiums are expanding freely and the roots may receive slightly more water than they have received since the full development of the past season's growth, but even at this stage the plants should be allowed to become fairly dry before watering them. Amongst the earliest to mature their flowers are D. moniliforme, D. Cassiope, D. endocharis, and D. aureum, whilst many of the earliest matured and rested plants of D. nobile, and many of its hybrids often produce flowers at an early date. The flowering season of these plants may be greatly prolonged by introducing some of the earliest specimens into heat, and retarding the later ones by keeping them cool, but it is not advisable to attempt this with choice and rare varieties It is still too early to attempt to flower the majority of Dendrobiums, and the plants should be kept from flowering until a later date, when, with the longer days and increased light, they will develop flowers of a much better quality. Any plants that are hastened into flowering should, after the blooms are over, be returned to their resting quarters until the proper growing season arrives.

Later Dendrobiums.—It is advisable to examine Dendrobiums such as D. Wardianum, D. crassinode, D. nobile and D. Ainsworthii, and any that may be showing for flowering should be placed in a slightly warmer house than the one in which they have been rested. After their removal from the resting house water should be applied at comparatively long intervals, as any undue excitement while the flower buds are developing frequently causes the new growths, now visible at the base of the pseudo-bulbs, to start into growth, and if these extend very far the whole crop of flowers will be lost. These remarks apply particularly to the shy-flowering D. Falconeri, whilst D. Wardianum and several others are susceptible to the same influence. There are many species of Dendrobiums which bloom later in the spring, such as D. Parishii, D. Bensoniæ, D. albo-sanguineum and D. superbum and its varieties. These, and many others, having completed their current season's growth, should be placed in the lightest and driest position possible, in a Cattleya-house temperature, during their season of rest. All of them should be kept dry at the roots until their flower buds show, when they may be removed to the warmest house. Shrivelling of the pseudo-bulbs should in all cases be guarded against.

General Remarks. — Odontoglossums in the cool house are in full growth, and care should be exercised to prevent the plants receiving a check. Many plants of O. crispum are showing their flower spikes, and they should be examined nightly for slugs. The cleansing of the houses and the plants should receive attention at this season, when other work is not pressing. Examine the plants thoroughly and wash the houses both inside and out, taking care to remove the filth between the laps of the glass to allow the atmospheric moisture that condenses to pass away, and thus prevent drip, which may do irreparable harm. Previous to re-arranging the plants, each one should be thoroughly cleansed, sponging the leaves and stems with an insecticide.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Permanent Figs.—Successional Fig trees to those forced in pots should be attended to, and all necessary work preparatory to starting the trees completed. With trained Fig trees covering a large area, it is difficult to retain a sufficient number of fruit-bearing growths without an excess of old wood. In pruning it is advisable to cut out by degrees old branches that can be spared and train in their places, thinly, young growths. Crowding the shoots will result in thin, spindly growths, and fruit of an inferior quality. White scale is a troublesome pest of the Fig, and is difficult to eradicate. The best specific is strong soft-soapy water mixed with a wine-glassful of paraffin. An old spoke brush is a handy tool for removing the scales where an ordinary scrubbing brush cannot reach them; a softer brush should be used on the young wood or the embryo fruits would be damaged. Beyond tying the trees in position, carefully examine any badly infested wood, and, if necessary, give a second application of the specific. Some insecticides of a soapy nature form a soapy froth during the process of scrubbing, which makes it most difficult to see if the pest is being removed. The addition of paraffin to the soft-soap solution prevents this, and the work is carried out more expeditiously. Trees that are very vigorous will not require manure. Where food is required by the roots, a concentrated fertiliser should be applied. In most cases a top-dressing of loam, mortar rubble, and bone-meal will suffice.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Potatos.—Where new Potatos are required very early in the New Year the pots should be prepared for planting the sets. Eight or nine inch pots that have been used for the growing of Chrysanthemum should be well washed and crocked. Place some pieces of grassy turf over the crocks to ensure efficient drainage. Prepare a compost consisting half of loam, chopped finely, and half good flaky leaf-mould, with a sprinkling of wood ash. Three parts fill the pots with this material and gently press three tubers into the soil in each pot. If the tubers have been stood upright in trays or boxes they should be well sprouted, and in the right condition for planting. Cover the sets with about an inch of soil and place the pots in a cool house. Lightly water the soil but do not give any more moisture until the haulm shows through. When the stems reach the top of the pots, topdress the plants with similar compost, and give water as occasion demands. Place the plants in as light a position as possible to ensure the growth being sturdy. Failing pots, ordinary boxes will answer the purpose, provided they are of sufficient depth. May Queen, Sharpe's Victor, and Midlothian Early are splendid varieties for forcing; the last makes rather more top than the others, but is a most reliable and good variety for the purpose.

Work in Frosty Weather.—Although much tillage cannot be done during very cold weather, certain operations may be forwarded that will help with this important work when more favourable weather prevails. Manure may be wheeled on to the ground that needs it, and all rubbish burnt to obtain a supply of wood ash. The soil yard should be made tidy, and fresh turves cut from a pasture and stacked in readiness for use in frames, seed sowing, etc. Continue to make hotbeds for forwarding early crops of Carrots, Turnips, Lettuce, and other vegetables. Sheds and store houses may be cleared out and the walls whitewashed. Potatos and other roots in store should be examined, discarding any that are diseased or in any way faulty.

PLANTS UNDER GLASS.

By JOHN COUTTS Assistant Curator, Royal Botanic Gardens, Kew.

Peperomia.—Very few species of this genus of stove plants are in cultivation at the present day. P. argyreia is the most commonly grown member and also the most useful from the decorative point of view. Its leaves are beautifully marbled with silvery white. They are stout and fleshy in character, lasting well when used for house decoration. Well-grown plants in small pots or pans are very effective for filling small receptacles. P. metallica is also very pretty, especially when several plants are grown together in a small, shallow pan; this plant differs greatly in habit from the former, being upright, branching and closely set with small leaves. During the summer the plants enjoy shade but during the winter months they should be exposed fully to the light. Peperomias are easily propagated by means of cuttings rooted in a warm house; as the shoots are of a fleshy character they root readily in an open bed.

Dracæna fragrans variety Victoriæ.—This handsome foliage plant has beautifully variegated leaves and is a great favourite for decorative purposes, large specimens being specially useful in large rooms and saloons. Plants that have grown tall and leggy, and have lost their bottom leaves, should have their stems cut half way through just under the lowest leaves, and a handful or two of moss tied round the cut stem. The moss should be kept moist by frequent syringings and the plant kept somewhat dry at the roots. Fresh roots will develop in the moist moss, and when sufficiently rooted the top may be cut off and placed in a suitable-sized pot. The plant that has been rooted should be grown in a close case for a week or so until it is established; if a suitable case is not available the plant should be stood for a time in the closest and warmest part of the stove or propagating house. The stems may also be used for propagating purposes, laying them in fibre in a warm propagating

Digitized by Google

case. When they have made young growths several inches in length the latter may be detached and rooted as cuttings. All Dracaenas and Cordylines are readily increased in this way. Old Dracaena plants afford a ready means of increase by using portions of the underground stems which have developed eyes; such portions of the stem are generally called "toes."

Paullinia thalictrifolia.—This slender climbing plant, with finely divided leaves resembling those of a Thalictrum or Adiantum Fern, is a very elegant subject for the stove house, the young leaves being bright rose in colour, changing with age to deep green. It is seen to best advantage when trained on a trellis, or neatly tied to slender stakes to form a specimen. This Paullinia succeeds in a compost consisting of good fibrous peat and loam, with sufficient sand to render the mixture open and porous. It may be propagated by means of cuttings inserted in pots of sandy soil, and plunged in a warm propagating case. Long sprays are very elegant and pretty for decorative work; for this purpose I would advise planting it out in a well-drained, raised bed, training the long growths up wires or fine string.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Pollination.—There being few Apples that are self-fertile, it has been recommended to interplant self-sterile ones with good pollenizers. Of the latter may be included Irish Peach, Cellini, Early Victoria, Lord Derby, Devonshire Quarrenden, Allington Pippin, Baumann's Red Reinette, Rival, King of the Pippins, Sturmer Pippin and Charles Ross. Bramley's Seedling is sometimes included, but here we had a record crop of this variety this season, and last year what was probably the smallest crop from large trees. Whether this was due to restricted activity of bees in the orchard last year I cannot say. Of those considered unfertile to their own pollen, Cox's Orange Pippin takes first place, whilst Beauty of Bath, Worcester Pearmain, Norfolk Beauty and Margil are of doubtful fertility.

Cherries and Plums.—The fruitfulness of these stone fruits year after year is undoubtedly due to cross fertilization, as numbers of varieties of these fruits are self-sterile. It is possible where this condition has not been studied when planting, that adverse seasons or conditions preventing cross pollination will be blamed. Those needing pollination by bees, or to be pollinated artificially, unless planted in proximity to self-fertile varieties, include, Cherries: Early Rivers, White Heart, Black Eagle, Black Tartarian and Waterloo. Plums: Jefferson, Kirke's Blue, Pond's Seedling, Coe's Golden Drop, Bryanstone Gage and Black Diamond. The varieties of Plums enumerated may be mixed with trees of Monarch, Czar, Denniston's Superb, Golden Gage, Early Transparent Gage and Reine Claude de Bavay, Morello Cherries, as is well known, set freely. The varieties Napoleon, Late Duke and Elton may be useful for inter-mixing with other varieties of Cherries.

Pears.—Provision should also be made in the case of Pears to ensure free setting of the fruits. In large orchards alternate rows of free and shy setters should be planted. Whatever method is adopted, care should be taken to plant varieties that will be in flower at the same time.

Pruning.—As the work of pruning proceeds any shoots required for grafting or use as cuttings should be selected and heeled in, and the remainder burnt forthwith. This will reduce the chances of spreading both disease and insect pests. The principal object of the pruner should be to prune in such a way that a well-balanced, symmetrical tree or bush is developed, with the branches well apart to allow air and light to enter the tree freely. Every endeavour should be made to obtain branches with fruiting spurs.

HARDY FLOWER BORDER.

POLYGONUM CAMPANULATUM.

THE majority of the Knot-weeds are best suited for shrubbery borders, on account of their robust and vigorous growth, but a few are well adapted for planting on the rockery on account of their miniature stature. The species in question is of neat, compact, bushy habit, with handsome foliage, and produces charming, Campanula-like, bell-shaped rosy white flowers in dense racemes, the blooms being delightfully fragrant. The plant grows from 2 to 3 feet tall and is well adapted for the second or third row in the herbaceous border. The flowering season is from August to October. This Polygonum is a useful plant for growing in a moderately moist and partially shaded position.

In common with many Polygonums, P. campanulatum (Fig. 129) produces underground creeping stems, but not so freely as in the Japanese P. cuspidatum. The best method of increasing the stock is by division of the clumps.

FIG. 129.—POLYGONUM CAMPANULATUM.

ERYNGIUM.

THE Eryngiums have a distinctly quiet steely-blue colouring that render them indispensable plants for border decoration from early August to late September and October. They succeed in good, deeply-trenched sandy soil, and a sunny position.

Their stiff, Teasel-like flower heads and spiny foliage borne on stout, rigid stems, produce a charming effect when the plants are mixed with or near the bronze foliaged Chinese Paeonies. The most showy of all are the new hybrids, Jewel and Violetta, of quite recent introduction. The former has numerous stout branching stems 2 feet high, surmounted with large flower bracts of a pretty bluish-purple, whilst the latter has large, clear, violet-purple inflorescences that are freely produced. E. amethystinum, E. Oliverianum superbum and E. Zabelli are useful, and very attractive with blue and steely blue flower bracts; E. planum is a taller growing plant of a distinct branching habit with small, pale blue heads; E. triquetrum has brilliant flower heads, whilst E. Spinalba with whitish heads and E. maritimum are both dwarfer growing, with a spreading habit. These last two are excellent for giving colour on the rockery or the front of the hardy flower borders.

The inflorescences of Eryngiums make very ornamental material when dried and placed in vases, and are especially useful in winter. *W. Logan.*

CHRISTMAS ROSES.

MOST gardeners are fully alive to the usefulness of these plants (*see* p. 338). Failures are not so much due to any inherent fastidiousness of the plants, but rather to either purchasing cheap plants or an excess of zeal on the part of the cultivator. Those who are anxious to grow these plants successfully should purchase strong, home-grown clumps and plant them as soon as possible. The flowers of the best white varieties do not equal the Eucharis in purity of colour, but are a good substitute for the same, and far more serviceable.

Where many growers err is in constantly lifting, shifting, and dividing their clumps. Large growers of these flowers for market certainly take great liberties with their plants, a breadth being annually cleared of their leaves, the roots lifted, and planted thickly under glass, in order to produce flowers for Christmas; but such growers have several large batches of plants of various ages and can afford to rest or split up any of their plants that have been exhausted by flowering. Private growers with a small stock of plants should grow their plants in such a manner as to obviate the necessity of moving them for several years.

Hellebores need a deep and fairly rich root run. A moderately rich loamy soil suits them best, although I have known them to do well in a brashy soil. A hot, dry soil or position is not suitable. Wherever planted they should be arranged in groups or patches, with a view to covering the plants with frames or hand-lights, as unless this is done the flowers will be splashed by the winter rains and, strange to relate, not last so long when cut. *James A. Paice.*

POLEMONIUM HIMALAICUM CAERULEUM.

THIS plant is commonly known as Jacob's Ladder, on account of the regularity of the bright, green side lobes of the foliage. It is perfectly hardy, a true perennial and of the easiest cultivation, producing numerous panicles of pretty, bell-shaped, clear sky-blue flowers. The variety P. h. album is equally effective on account of its pure whiteness. The plant grows 3 feet tall. *W.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

PELARGONIUM ROLLISSON'S UNIQUE.

AS several correspondents have lately referred to this very old, scented-leaved Pelargonium (see pages 84, 107, 136, 163, 177, 191, and 236), a few notes on its history and its sporting propensity may be of interest to readers. This plant (Fig. 131) has been grown here for the past five years, but up to the present has not produced any variation in its flowers. The spelling of the name, however, should be Rollisson's, not Rollinson's, as given by some correspondents. The origin and precise date of its introduction does not seem to be known.

Donald Beaton was of opinion that the plant originated as a seedling from P. capitatum (figured in the *Bot. Mag.* tab. 7346 as P. Drummondii). In *The Cottage Gardener*, so far back as 1856 (vol. xvi., p. 4) Beaton refers to this plant as the old Purple Unique which shows that even at that date it must have been an old plant. The plant figured in *Sweet's Geraniaceæ* (vol. iv., tab. 371) as P. Rollinsoni clearly does not represent the plant now under consideration. A good figure of Pelargonium Rollisson's Unique will be found in *The Garden*, 1887 (vol. xii., p. 491, and further notes in vol. xix. (1881), pages 214 and 332. The following extracts from *The Gardeners' Chronicle* will throw some light on the history and tendency to "sport" of P. Rollisson's Purple Unique:—

GERANIUM SPORTS.—"I beg to send for your inspection flowers from two plants of Rollisson's Unique Geranium, each of which produced the purple and lilac flowers sent, in one instance, as you will observe, the two colours are united in the same truss. Is this sport a common occurrence? . . . *R. P., Pinchos*, Anglesey."—*Gard. Chron.*, 1861, p. 578).

GERANIUM SPORTS.—"Your correspondent *R. P.* (see page 578) asks if a lilac sport on Rollisson's Unique is uncommon. I think not, as I have frequently had the same sport appear on it when growing strongly in pots under glass, some branches producing all lilac flowers. Half the truss has also some crimson and the other half lilac, as mentioned by *R. P.* . . . *W. Heale*, Westerham, Kent."—*Gard. Chron.*, 1861, page 600.

EDITORIAL NOTE IN GARD. CHRON., 1861, page 925.—"Do any of our readers happen to know the origin of the Pelargonium which we believe is generally called Rollisson's or the Purple Unique? The variety to which we refer is one which though of rather straggling habit has bold "Oak" leaves and deep purple flowers, and is a great favourite in flower gardens and for general decorative purposes. We presume it owes its origin, as many such varieties do, to a sporting branch, in which, however mysterious it may seem, the character into which it has sported has become fixed. . . . Among the plants grown at Chiswick was a group of Pelargoniums of the class to which this unique variety belongs, and in this group were plants of the Purple Unique and of another, we believe the old Lilac Unique, differing only in having the flowers lilac instead of purple. On a plant of the latter we observed one truss of flowers in which half the number were of the purple colour, to which reference has been made, and the other half were lilac. The two colours, though in separate flowers, were not scattered promiscuously throughout the truss, but the blossoms and buds on the other side were purple, while those on the opposite side were lilac."

FIG. 130.—PELARGONIUM MDME. SALLEROI (LEFT), AND A GREEN-LEAVED SPORT THEREFROM (RIGHT).

SPORTING PELARGONIUMS—ROLLISSON'S UNIQUE, &C.—"The Lilac Unique was first sent out by Wm. Ivery of Peckham, and originated in the shape of a sporting branch by a gardener on Peckham Rye from a plant of Rollisson's Unique. It is pretty and useful, but not so handsome as the parent. Rollisson's Unique no doubt originated with the father of the present proprietors of the Tooting Nursery, but whether from seed or by a sport it is impossible to say. Whatever may be its origin, Pelargonium Daveyanum was one of its parents, and from the identity, if not the positive sameness of the foliage and habit of the plant, I strongly suspect it to be a sport from that variety, and my impressions are intensified by the fact that it is exceedingly difficult, if not impossible to get Daveyanum to set seed; indeed, I tried my utmost some years back, but failed. The downy foliage, the style of the truss (though much larger than Daveyanum), the colour of the flowers and straggling habit, all point to Daveyanum as one of its parents and cross-bred; perhaps P. concolor, which Sweet describes as a strong grower, suitable for training to trellis-work, was the other parent. There are in the trade two varieties of Rollisson's Unique, one a stronger grower and much superior kind to the other. There are also varieties of the Scarlet Unique, one an old Oak-leaved kind called Defiance, and the other, though a much stronger grower, I still suspect to be a sport from Rollisson's, for in the sporting flowers of both varieties the identity of colour of the lilac flowers was complete. The Scarlet Unique, as far as ever I could ascertain, is of Continental origin, having come to this country either from France or Belgium. It is a strong constitutioned, small trussed, loose growing kind, but does not make such an effective specimen as the best variety of Rollisson's Unique, which is really, in a decorative point of view, a most excellent plant." *P. A. W. Gard. Chron.*, 1861, p. 945.

PELARGONIUM PURPLE UNIQUE.—"I have always supposed that this was a cross obtained by Mr. Rollisson from P. quercifolium and another Cape variety. As to its sportive character I can bear ample testimony, and I know of stranger instances than that at the Horticultural Society's Garden at Chiswick. There are to my knowledge four distinct sports from Rollisson's Unique:—1st, Lilac; 2nd, Conspicuum (rose-crimson); 3rd, Coccineum (red), 4th, Rose d'Amour (rose); this last is a sport in the second degree from Coccineum. All these may now be considered fixed varieties, although they will occasionally produce flowers of the original colour. This year Coccineum has pushed three different colours, red, rose and lilac upon the same truss, and upon other trusses are flowers half red and half lilac; other Geraniums are also subject to variation, not only as regards colour and foliage, but also in habit of growth and dimension of leaves; the diminutive variety called Variegated Dandy is, singular as it may appear, nothing but a sport from one of the old large-leaved Scarlets. Accident made me acquainted with the fact. When it was first

Digitized by Google

sent out I planted it in the open ground; towards the end of the summer I perceived by its side a strong shoot of a large green-leaved Geranium; supposing this to have been from an old root which might have been accidently dug in, I pulled it up and to my surprise I found it to be a sucker from Little Dandy; before mentioning this to Mr. Thompson, he told me that I was quite correct in my supposition, and informed me of the way in which he had obtained it. The Variegated Dandy is subject to other changes; very frequently it loses its variegation, but retains its Lilliputian habit. Dahlias, Chrysanthemums and many other plants present the same plastic tendency to variation both in leaves and flowers. In 1848 I raised a Chrysanthemum (Queen of England) which has produced six distinct sports, four in colour—blush, rose, yellow and white—and two in foliage, all of which have now become fixed. . . .—*John Salter*, Versailles Nursery, Hammersmith." *Gard. Chron.*, 1861, p. 968.

NOTES BY WM. PAUL.—Your correspondent *P. A. W.* is right in assuming one of the Scarlet Unique Geraniums to be of Continental origin. Many years ago, when travelling in France, I saw this Geranium growing among a lot of seedlings in the nursery of M. Boucharlat at Lyons, and bought it and sent it home, naming it Scarlet Unique. About the same time Mr. Gaines, of Battersea, raised or obtained a similar one, but not the same, and named it Scarlet Unique, neither he nor I knowing of the existence of the other. There is a fine plant of my Scarlet Unique in the conservatory at Camfield Place in this county, the seat of the Hon. Baron Dimsdale. —*Wm. Paul*, Nurseries, Waltham Cross, Herts." *Gard. Chron.*, 1861, p. 968.

NOTES BY J. SHEPPARD.—"Rollisson's Unique Pelargonium . . . One of the old plants threw out a sport last summer that has lilac-coloured flowers, that will, I think, be worth perpetuating. In beds Rollisson's Unique is too rampant a grower to flower freely, unless restricted by cramping its roots in pots, but for vases or boxes, where it can hang over, it has a fine effect. . . . *J. Sheppard.*" *Gard. Chron.* 1876: p. 84.

NOTE BY F. J. HOPE.—"This is very apt to sport as described on page 84. About twenty-five years ago the Lilac sport went under the name of Glorianum or Lilac Unique . . . *F. J. Hope*, Wartie Lodge." *Gard. Chron.* 1876., p. 180.

P. Glorianum is figured in *Sweet's Geraniaceæ*: vol. 5, tab. 82.

NOTES BY R. D.—"That fine old Pelargonium, Rollisson's Unique . . . How it originated is involved in some obscurity, but it is generally regarded as having sprung from a cross made at the Tooting Nurseries, between P. quercifolium and another Cape species. It has proved of a very sporting character, having thrown several of these, all more or less valuable in the hue of the flowers. Some years ago as many as four distinct sports were in cultivation, namely, the Lilac; rosy crimson known under the name of Conspicuum; Coccineum, red: and Rose d'Amour, rose. . . . Those now best known to cultivators are Aurora, bright glowing crimson, the upper petals darkly spotted and blotched with white; Conspicuum; Crimson Unique; Diadem, rich violet crimson, dark upper petals, flowers very large and good quality; Lilac Unique; Scarlet Unique, known also as Macbeth, which appears to be a fine form of it; and the White Unique. . . . *R. D.*" (*Gard. Chron.* 1876., p 714.

REPORT ON PELARGONIUMS GROWN AT CHISWICK 1861, BY THOMAS MOORE.—"Rollisson's Purple Unique from Messrs. Fraser—Leaves deeply blunt-lobed; flowers deep, rose purple, spotted. One of the most useful of the hybrid bedding class, and an excellent conservatory plant. Some of the branches produced trusses of both lilac and purple flowers, and on one truss both colours were produced, one side of the head having lilac flowers, the other purple." Extract from the *Journal* of the Royal Horticultural Society, vol. 2, 1862, p. 149.

Pelargonium Variegated Dandy referred to by John Salter in the above extract, is also known in gardens as Dandy and Madame Salleroi (Fig 130), &c., a very popular plant, of dwarf habit, and much used as an edging to other plants in a scheme of "bedding-out." In its normal condition, *i.e.*, dwarf, compact, and with a white margin to its leaves, it never produces flowers, but, as stated by Salter, it sometimes produces green sports. These sports are of three kinds:—

(i) Having plain, green leaves.

(ii) Having whitish centres to the leaves (reversed variegated), masked by a green skin. Both these sports grow very tall, so much as three feet, and flower very freely. The flowers are very small and dark pink in colour. These have no pollen and have proved sterile to pollen from various plants.

(iii) Having white shoots and leaves which eventually die.

The flowers are not distinguishable from those produced by Mangles's Variegated, which also produces green-leaved sports exactly similar to the green-leaved sport of Madame Salleroi or Variegated Dandy.

The illustrations in Fig. 130 show a typical plant of Madame Salleroi and a green-leaved sport which originated from it. *A. Hosking, The John Innes Horticultural Institution, Merton.*

THE ROSE GARDEN.

ROSE SENSATION.

THE new red Rose Sensation, raised in the United States, has been awarded several honours at exhibitions in that country and trade growers there are planting it extensively for market purposes. The *American Florist* for December 1 has a splendid full page illustration of a large house filled entirely with this variety and all the plants are carrying an excellent crop of fine blooms.

FIG. 131.—PELARGONIUM ROLLISSON'S UNIQUE.

The raisers' description, who state that it is a hybrid between Premier and Hoosier Beauty, is as follows:—"As large and more prolific than Premier. Well supplied with a heavy luxuriant foliage. The flowers are fine any season of the year. The colour is an entrancing shade of red. The bud is long, pointed and the open flower beautiful, with extreme size and good colour to the last. The stems are long jointed and strong with ample foliage. A good keeper and shipper. Grafts well; roots well and above all else, grows well. Properly grown it will produce more dollars per square foot of space than any other Rose of to-day." The Jos. H. Hill Co., of Richmond, Indiana, U.S.A., is placing the variety in commerce in February next and several well-known American Rose firms are assisting Messrs. Hill and Co. in the distribution of this new Rose, which has created quite a sensation in America.

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

RASH indeed would be the amateur who should attempt to forecast the vagaries of the British climate more than a very few hours ahead; yet there are certain phenomena that the accumulated experience of generations has taught country dwellers to regard as the forerunners of a definite type of weather. Among these phenomena is that which has prevailed over most of our island since early in November—snaps of frost, interrupted every two or three days by a quick rise of temperature. Such alternation, prevailing for several consecutive weeks, is spoken of by our local weather-wise folk as "feeding a frost," and is regarded as presage of long, hard cold. We are warned, therefore, to expect some such visitation after Christmas. If this does not come, faith in rural weather-lore may be shaken; if it does happen, there is likely to be mischief wrought among the large number of new species which a series of exceptionally mild winters has tempted us to treat as hardy plants.

Meanwhile, although it is not wise to attempt planting under present conditions, even where in mild maritime districts the soil may be soft enough to admit of it, there are many minor operations which may be attended to. One of these is propagation of the Giant Lily —L. giganteum—whereof the lofty candelabra of lusty capsules stand to remind one of fragrant summer evenings. These tall, tawny stems, carrying aloft a plentiful harvest of ripe seed, are so ornamental that one feels unwilling to displace them. Nevertheless, they provide the speediest way to secure a stock of this fine Lily. Seed germinates rapidly, but one must wait six or eight years before being rewarded by a flower from a seedling; whereas if the old stem is firmly grasped and pulled steadily up, a number of young bulbs, some of them five or six inches long, will be found clustered among the stem-roots of the old bulb which has disappeared after flowering. Some of the larger of these young bulbs will flower in two or three years, and it is a positive advantage to them to be released from the struggle for life with their companions. The one unsatisfactory feature in this prince among Lilies is the brief duration of its bloom. One must wait years before a bulb sends up a flowering stem, and when it does so to any height from six to twelve feet, with perhaps a dozen great blossoms on it, these retain their beauty and fragrance barely more than a week, and the bulb that has given them birth expires from the effort.

There is no genus of bulbous plants less exacting in cultivation than the Colchicums, yet one seldom sees the best use made of them for the embellishment of pleasure grounds. In flower borders—yes; usually our native C. autumnale—but there are several much finer species, none of which is seen at its best in such a position. They are, indeed, unsuitable for the borders in more ways than one. The winds of autumn bruise the fragile flower stems and rain splashes soil upon the blooms: while the exorbitant foliage that rushes up in spring makes a sad mess when it flags and fades in summer, to the detriment of less vigorous neighbours. Colchicums never show to such advantage as on grassy slopes, provided these are fully exposed to sunshine, for the plants are impatient of shade. Daffodils and Crocuses thrive and spread freely under deciduous trees, which are bare when these bulbs put forth their flowers, but cast too deep a shade when the autumnal Colchicums spangle the Alpine pastures.

Perhaps one reason why more and better use is not made of Colchicums is that when most amateurs and gardeners fill up their orders for bulbs, that is just the time when the plants are busy flowering. Neither can they bear transport in spring, for then the great sheaf of leaves is pushing up, bringing with them the fat, three-celled, many-seeded capsules that have formed underground during the winter. But there are two seasons when the bulbs may safely be raised and re-planted—at midsummer, after the foliage has withered, and at any time between November and February (the earlier the better), provided there is no frost. The soil is in better condition for the operation in open winter weather than in summer, when it is apt to be inhospitably dry. About thirty species of Colchicum are recognised by botanists, but C. giganteum, B. Bornmülleri and C. speciosum are probably the pick of the set. I confess that I cannot distinguish between them with any confidence; they are all large-flowered and make a splendid display on a sunny September day, and I care little for the smaller species, except a lovely little rose-tinted kind which I dug up near the king's palace at Cettinge, in Montenegro (there *was* a King of Montenegro till the war threw the *Almanach de Gotha* into printers' pie). It flowers in August and must be submitted some day for identification to Mr E. A. Bowles.

Colchicums—those species, at least, which we grow here—multiply with extraordinary rapidity. It does not seem many years since I paid pretty smartly for three bulbs of the peerless white variety of C. speciosum; now we could make a barrow load of their progeny. Colchicums are so usually spoken of as autumn Crocuses that, at the risk of being blamed for commonplace, I may venture to remind some of those who grow them that they belong to the Lily Order, with six stamens, whereas the Crocus is of the Iris Order, with only three There is a beautiful coloured plate from the late Mr. Moon's water-colour drawing of Colchicums in Mr. Robinson's *Flora and Sylva*, vol. i, p. 108.

Paeonia Mlokosewitchii, handsomest of all yellow Paeonies, is already thrusting crimson shoots above ground, despite nine degrees of frost.—*Herbert Maxwell, Monreith.*

BULB GARDEN.

ALSTROEMERIAS.

THE members of this small genus of the Amaryllis family are chiefly natives of Chili, Peru and South America and have in many cases, because of this origin, been given greenhouse treatment, which did not conduce to success. The first Alstroemerias were raised in this country from seed at Kew, in 1753, through the instrumentality of Linnaeus who had been given some seed by Baron Alstroemer. Such kinds as aurantiaca, lutea, chilensis, hybrida, and one or two others are quite hardy if planted six or eight inches deep in a dry soil, and will take care of themselves and flower freely year after year. The two best known, other than the hardy ones, are A. Pelegrina alba and A. P. rosea. It is sometimes recommended to plant these outside at the foot of a south wall. This may be suitable in Devon or Cornwall, but the risk is too great near London. However, the plants will do well in a cold frame or Alpine house and if potted in light soil will give plenty of flowers and are two of the choicest kinds.

The hardy sorts are best grown in beds and if the chilensis hybrids are chosen, many shades of yellow and red will be represented. A dry, well drained, and a sunny situation should be given them and a soil rich and deep. If planted at the suggested depth the roots will grow down from any danger of frost. Planting may take place as soon in autumn as the tubers can be obtained. The flowers are produced in summer; they are most attractive and last a considerable time when cut.

It is an interesting business to raise Alstroemerias from seed which should be sown preferably in the spring. The seedlings will flourish out of doors in a warm and dry corner, but should have a slight mulching during the first winter to protect them. The young plants may, after the first year, be planted in their flowering quarters. There is no trouble in obtaining seed as it is generally plentiful. *T. D. T.*

CULTURAL MEMORANDA.

PLANTING HARDY FLOWERS.

PLANTING is often a serious problem to the uninitiated, but to the hardy plant enthusiast it presents no difficulties. He will plant at all seasons, excepting when a plant is too far advanced towards flowering, or during very frosty weather. The general seasons for planting, however, are autumn and spring.

In arranging a hardy flower border, the scheme of planting should be well considered, with a view to keeping the border furnished with flowers from spring until autumn. It is impossible to maintain a blaze of bloom all the time, but much may be done by cutting out the old flower stems as the blossoms fade, thereby ensuring a succession of secondary flowers.

Good clumps of one colour show up much better and are more defined than a mixture, but combinations of two colours may be admitted, and they look very charming. The arrangement of colours is a matter of individual taste, but there are certain rules that should be observed, the chief of which is to commence with mild colours at the approaches to the border and gradually pass into the strongest colours in the distance.

In grouping a hardy flower border the majority of the tallest plants should be placed towards the back part; in fact, a graduated scale of height should be observed from back to front, with here and there taller subjects rising above the others to obviate severe formality.

Between clumps of Phloxes, Asters, or any late-blooming plants, Daffodils, Fritillaria Meleagris, and late-blooming Tulips may be planted; in fact, bulbs should occupy an important part in the composition of the hardy flower border.

The first step towards planting is the preparation of the ground, and whether there is a whole border to plant or only a part of one the same rules should be observed. The drainage should be thorough, and the fertility of the soil adequate to supply the demands of the plants for several years. The ground should be trenched at least two spits deep, and a good layer of either old hot-bed manure, or old cow manure put in the bottom, and another layer placed between the two spits. Wood ash and bonemeal may be mixed with the soil as the work of digging proceeds.

When the border has been dug, a dressing of lime lightly forked under the surface will be beneficial to the plants.

Do not plant for a few hours after rain has fallen, and never plant on hard ground to save the trouble of forking it again. Make a hole large enough for the reception of the roots, and be sure that the soil is firm about the latter. *James A. Paice.*

PRUNING OF THE APRICOT.

ALTHOUGH the practice of some is to defer the pruning of Apricot trees until the spring, I know of no reason why this operation should not be done in mild weather during the autumn and winter.

As is well known, the Apricot is very susceptible to injury caused by the pruning of strong branches, but if the usual stopping of the breast growths was done by hand during the early summer, little if any pruning at this time of the year should be necessary.

Where winter pruning is needed always retain fruitful shoots as near the base of the stem as possible, removing lateral shoots that appear to be unfruitful. All the natural fruit spurs on the two-year or three-year old wood should be preserved, and the end or terminal growths shortened according to their strength, disposition of the buds, and the spaces that need furnishing; keep every part of the tree open, allowing sufficent space between each branch to allow both sunlight and air to enter freely. *W. Hedley Warren.*

TREES AND SHRUBS.

DIERVILLA FLORIDA.

THE most popular of all the species of Diervilla is D. florida, a Chinese plant introduced to cultivation in this country so far back as 1845. The collector of the species was Robert Fortune, and the plant was introduced by the Royal Horticultural Society. Few flowering shrubs excel D. florida in grace or in freedom of flowering, and as it appears to thrive in most parts of the country and in various soils there is small wonder that it is found in comparatively small gardens as well as in large groups in extensive public and private gardens. It is best known, however, as Weigela rosea, the name given it by Lindley, but which is now superseded by Siebold's name of Diervilla rosea. The accompanying illustration (Fig. 132) shows a specimen in Mr. C. Cockcroft's garden, near Rochdale, and well illustrates the natural elegance of the shrub and the profusion with which it produces its funnel-shaped, rose coloured flowers. These are borne in threes or fours at the ends of short, side shoots and appear during May and June. The variety candida has pure white flowers, while D. Looymansi aurea has yellow leaves, and D. f. variegata has its foliage margined with pale yellow. This last is a very attractive plant and has deep rose coloured flowers. A dwarf form, named nana, has paler flowers and lighter yellow edges to the leaves. *C.*

SOME GAULTHERIAS.

THE genus Gaultheria comprises a large number of Ericaceous shrubs, of which only a small proportion are in cultivation in this country. The better known among these latter are all peat and moisture lovers and fond of cool, half-shady situations. In such spots, whether in the rock-garden or woodland, they are always attractive on account of their pretty or unusual evergreen foliage, their Heath-like waxen flowers or their conspicuous and often handsome fruits.

The largest and most familiar of these Gaultherias is G. Shallon and it is also the easiest to cultivate, thriving abundantly in any damp, lime-free loam. This species, which was introduced by Douglas from N.W. America over a century ago, makes a dense thicket of upright, reddish stems 2ft. to 4ft. high, amply furnished with large heart-shaped, Apple-green leaves. The flowers, borne in early summer in racemes some 3 inches long, are of the characteristic urn-shape of the Ericas and pinky-white in colour. A well-flowered specimen of G. Shallon is an object of no little attraction in the woodland or wild garden. Since it spreads, though not always rapidly, by underground shoots and resents disturbance this is a shrub that should be given plenty of space.

G. Veitchiana, one of Mr. E. H. Wilson's (1907) Chinese introductions makes a close-set, tufted little bush less than one foot high. This species appears to need a moister soil than the above, a sandy peat or damp vegetable loam with leaf-mould suiting it admirably. The foliage of G. Veitchiana consists of rough, deeply veined, wrinkled leaves averaging about 2 inches in length. These are a dark, often bronzy green, oblong and with a breadth of about half their length. The flowers of this species, produced in axillary racemes, are white and very effective against the dull foliage and rusty fur of the branches. The fruits which follow these are about the size of a small Currant and a deep china-blue.

Perhaps the oldest Gaultheria known to our gardens is G. procumbens, the Creeping Wintergreen, or Partridge-berry, of N. American woods. This is a delightful little plant for covering the ground between dwarf Azaleas and other shrubs of the sort, its tufty growths seldom rising more than 6 inches. Although it spreads like others of its kind by creeping roots it is of slow growth. The leaves of G. procumbens are a dark glossy green, leathery in texture, obovate and about 1½ inch in length. If crushed they emit the well-known aromatic odour of oil of Wintergreen which is, or was, extracted from this species. The pretty, pinky-white flowers of G. procumbens appear singly underneath the leaves in the late summer, the succeeding fruits being much like those of the Holly in colour and size. Since these seem to be distasteful to birds and mice they will often remain on the plant throughout the greater part of the winter. G. procumbens, though delighting in peat, will thrive in ordinary cool loam with which plenty of leaf mould has been mixed. In habit and general appearance this species somewhat resembles Epigaea repens, another plant that loves shade.

G nummularioides is a Himalayan member of the genus, quite hardy and one that, despite its attractive qualities and ease of culture, is still uncommon. This species makes a dense, rounded, cushiony mat of foliage, the long and prostrate stems, covered with red-brown bristles, being furnished with heart-shaped, dark-green leaves. These are raspy to the touch, closely-set in pairs, and they gradually diminish in size towards the extremity of the growth. But for their difference in colour and texture they might be said to resemble those of Lysimachia nummularia. Though G. nummularioides spreads by underground shoots it does not do so with us to any extent, quite an old specimen being no more than a couple of feet across and a compact mat of foliage from which the long, trailing shoots extend, lying closely pressed against the mossy rocks or stumps amid which this plant delights to dwell. This species is entirely a foliage plant and one admirably suited for associating with Ferns and other woodland subjects of the kind. Its flowers are inconspicuous and here it never ripens its fruit.

Another Himalayan species of equal hardiness and certainly of no less charm is G. trichophylla. This pretty little plant creeps about by means of fine, underground stems, making a Heath-like carpet of slender, semi-prostrate growths some 3 inches or 4 inches in height. The reddish stems are furnished with tiny leaves, slightly hairy, ¼ inch in length and about half as wide, with blunt ends. The foliage is a rich, glossy green which is most attractive at all seasons. The berries which follow the pink, bell-shaped flowers are enormous for so small and frail a plant, being about the size of a sparrow's egg and of a clear turquoise blue. This beautiful species is quite prosperous with us in ordinary well-drained, woodland loam, with leaf-mould. Though it will do in shade, it undoubtedly enjoys some sun. A cool, moist root-run beneath some thin-habited deciduous shrub seems to suit it best.

Like most members of its race, Gaultheria trichophylla resents disturbance. It is best left alone for years when well-established and in planting it is wisest to use pot specimens or clumps.

Gaultheria pyrolaeoides is a very lovely little shrublet of some 8 inches in height with glossy green, oval, sharply-pointed leaves and pure white berries as large as marrowfat Peas. But as this is among the later arrivals of this genus to our garden I cannot write further of it from my personal experience. *A. T. Johnson, Ro Wen, Tal-y-Cafn, North Wales.*

VERONICA PEDUNCULARIS.

This Veronica is a little plant of distinction and much merit, and although it is quite hardy and easy to grow in any light soil in a sunny spot it seems to be very uncommon both in gardens and nurseries. From a low mat of pale green, often bronzed, leaves, which are remarkably like those of our own V. Chamaedrys, this species sends up in spring numbers of extremely elegant flowering sprays which bear on their many slender branches pure white flowers lined with rose. These blossoms are about the same size as those of V. Catarractae, but they are produced in such extraordinary abundance as to almost smother the plant. This amazing yield is not only maintained for some two months, or more, in the late spring and early summer, but if, after flowering, the stems are cut back and the plant well watered it will give another display in autumn

The plant I have of this species was given me by Mr. E. C. Buxton who obtained his original stock from the late Mr. Wolley Dod, who, it is said, found the plant on a roadside in Hungary. For some years it was catalogued by a nurseryman—presumably the only one who had it—as "Veronica sp. E. C. Buxton"—much to the latter's amusement! Later, I think in 1914, the species was identified by Kew as V. peduncularis of the Caucasus. *J.*

INDOOR PLANTS.

SOME BEGONIA SPECIES.

MANY species of Begonia are well worth growing for decorative purposes. Their graceful habit, the profusion of delicate male and female flowers—typical of the family—and the richly variegated foliage of some, are qualities that make them useful subjects for the warm and intermediate houses.

A well-grown plant of B. manicata is very beautiful. This species was introduced to England from Mexico during the earlier part of the nineteenth century. The light and fairy-like flowers, produced in great profusion, give it a foremost place among Begonia species even to-day, and yet with a fairly warm temperature it is easier to cultivate than many others. Kew makes a speciality of B. manicata, and it is a feature of the greenhouse there during the early Spring. This species has growth of a somewhat succulent nature; the leaves are smooth, massive, and solid looking. The flower scapes average from two to four feet, varying in accordance with the size of the plant and the pot it is grown in. No special method of cultivation is necessary for B. manicata. An ordinary potting compost is all that is required, but care should be taken to render the soil open in texture by the aid of broken crocks as well as sand. Good drainage is essential, for the plants are evergreen and require water and nourishment at all seasons. B. nitida is the oldest introduced species. It is an almost perpetual bloomer, and the flowers, of very pale pink, are delicately scented. As a stage plant for the conservatory, B. nitida never fails to please.

B. acuminata, another perpetual-blooming species, produces its flowers much more profusely than the last named; a batch of this species on the stage of an intermediate house will always give a striking and prolonged effect. Like all Begonias, it requires much care in watering, otherwise, in a moderate heat B. acuminata is not difficult to cultivate. The plant may be raised readily from cuttings.

B. coccinea, a native of Brazil, is a beautiful species with a habit well adapted for training up pillars and rafters of a warm house. The Bamboo-like stems grow with amazing rapidity, and the numerous blood-red flowers on drooping penduncles are picturesque and durable; the leaves, too, are effective, a refreshing green in colour, somewhat succulent, and almost pointed in shape.

Another species remarkable for its graceful habit and usefulness as a plant for covering pillars and walls is B. fuchsioides, brought to this country from New Grenada in 1846. The bright scarlet, pendulous flowers of this Begonia are very like those of the Fuchsia, and are produced in great profusion on a well-grown plant. The tall stems are woody and the leaves small and numerous. It should be grown in a good peat border with liberal root room, and a happy medium between wet and dryness should be maintained, for this particular species will not tolerate careless handling of the water-pot; a little too much water and the leaves will very soon turn yellow and drop off, whilst drought at the roots is equally harmful, the only difference being that the leaves just drop off without changing colour or even wilting.

B. Evansiana is a useful pot plant, originally found in China, and in a few other countries since. It is tuberous, with annual stems; the rose-coloured flowers are borne on slender, axillary stalks, and these, together with the leaves of uncommonly blended red and green shades give a pleasing effect. Bulbils are numerously produced in the leaf axils of this species, and propagation is an easy matter.

B. natalensis and B. Sutherlandii are tuberous species with habits that are very similar. In the former the leaves are small and mottled and the flowers white: the latter has leaves that are tinged with red, and salmon-red flowers.

B. Rex is not seen so frequently in gardens as formerly; it was much favoured at one time. It is a beautiful species with rose-coloured flowers and variegated foliage, the leaves having dark green edges and centre with a silvery belt between. Many varieties with leaves even more gaily variegated than the type have been raised.

B. Dregei and B. socotrana were made famous when M. Lemoine obtained the annual-stemmed hybrid, Gloire de Lorraine, as a result of crossing the two species. B. socotrana had proved a useful breeder, it seems, ever since its introduction from Socotra in 1880, for there are numerous hybrids between it and other species, all of them good garden plants.

To make merely a passing reference to the species B. Schmidtiana, B. polyantha, B. macrophylla, B. glaucophylla, B. Haageana, B. boliviensis, and B. octopetala does them an injustice, yet much space would be necessary to discuss them in detail. *H. W. Stenning.*

TWO USEFUL GREENHOUSE PLANTS.

Lapageria rosea, a Liliaceous twining climber introduced from Chili in 1847, is eminently suitable for the cool greenhouse. It resents fire-heat and will withstand a few degrees of frost under dry conditions.

For this plant a compost consisting of a mixture of rough peat and loam with plenty of sharp sand and charcoal intermixed is advisable. The rooting area should be moderately restricted and perfect drainage is essential. During the plant's season of active growth frequent and heavy syringings are necessary to keep down attacks of insect pests, and in the hottest months shading is beneficial.

It should be trained on wires under the roof, not too near the glass. The rich rosy-crimson, pendulous flowers are borne in the axils of the leaves of the lateral branches and at the apices of the branches. They are produced in profusion, frequently overlapping each other in string-like inflorescences, the effect of which is magnificent. The wax-like consistency of the flowers enables them to persist over a very long period, thus making the plant extremely valuable from the decorative point of view.

Sparmannia africana, an arborescent South African shrub, is another old plant of considerable merit for the cool greenhouse. It was introduced in 1790 by Dr. Andrew Sparmann, in whose honour it was named. It is a handsome, quick-growing, Malva-like shrub with large, soft, hairy, cordate leaves and white flowers — with prominent yellow stamens—borne in terminal umbelliform cymes.

It is a gross feeder, and should be given a rich compost. If planted in a border with unrestricted root-run it quickly attains a height of 10 feet. Grown in pots it needs a receptacle of fairly large dimensions and should be fed liberally as soon as the roots become pot-bound.

Cuttings inserted in sandy soil and placed under a glass in heat root readily. In view of its ease of propagation and quick growth it is a most useful plant for sub-tropical bedding. *W. A.*

ROUPALA POHLII.

This handsome foliage plant, which is sometimes known as R. corcovadensis, is usually afforded stove treatment, whereas it succeeds perfectly in an ordinary greenhouse; in fact, it will grow all the year round in a cool living room. It is surprising that this fine plant seems to have been completely over-looked for decorative purposes, big specimens being very effective in large, lofty rooms. Like most members of the natural order Proteacea, this Roupala is by no means easily propagated: the cuttings take a long time to root, generally about six months. The more slender side shoots should be selected for use as cuttings, and they should be placed singly in small pots containing sandy soil. The pots should be plunged in a warm propagating bed in a house having a temperature of about 60°. Once rooted their subsequent cultivation presents no difficulty. *C.*

VEGETABLE GARDEN.

EARLY DWARF BEANS.

KIDNEY BEANS may be had practically the year round and, for the earliest crop, preparations for forcing should be made with the turn of the year. When forced, the plants are usually grown in large pots, although where heated pits are available they will give excellent results in beds of light loamy soil. In the early stages of growth a temperature between 55° and 60° is sufficient, but when three or four leaves have formed the warmth should be raised to 70° by day in the absence of sunheat. The plants should be exposed to all the light possible and grown in a genial atmosphere, with as much ventilation as the weather permits. Red spider is the greatest enemy of Beans grown indoors and the syringe should be used freely on the undersides of the leaves to keep the pest in check. Healthy plants respond to liberal feeding after the flowers have set.

In most localities it is not necessary to use fire heat after March is well in, but to grow the plants in cold frames. The frames should be placed in a sunny, sheltered situation. In order to insure perfect drainage the pots should rest on a layer of strawy litter. Failing this, very light garden soil, or loam of an open texture should be provided to a depth of about nine inches. In all cases heavy soil should be made lighter by a liberal addition of charred refuse, fine rubble and manure from an old Mushroom bed. Sow the seed in drills made one foot apart and in sufficient quantity to leave the plants standing six inches apart. Water the roots sparingly until they have become well established, and ventilate the frame without admitting cold draughts. Make the most use of sunheat by closing the frame early in the afternoons, and in the case of frost have mats in readiness to cover the lights. Watering and feeding should be done carefully, especially when the plants are passing out of flower and onwards.

To obtain Dwarf Beans very early in the open, raise the plants in cold frames either in boxes, or pots. I prefer the latter method as it enables planting out to be done with the least possible check. Sowings may be made in this manner from the middle of April, or even earlier, in favoured districts. The plants should, however, be allowed to develop steadily, as forcing results in the foliage becoming very tender and liable to injury from cold on being placed in the open.

A warm border should be selected for this early outdoor crop and the plants should be transplanted about the middle of May; if means of protection can be provided from cold winds and frost, so much the better. The usual time to sow in the open varies, according to the district, from the end of April to the end of the first fortnight in May. The plants are not fastidious, although there is an appreciable difference between their behaviour in rich, light soils and those on the heavy side, therefore light material of whatever kind available should be freely employed in order to create a suitable rooting medium.

Varieties differ in their habit, but an average distance of twenty inches between the rows and ten inches between the plants is suitable. These distances refer to main crop varieties; early sorts will do quite well in double rows made about six inches apart, allowing a distance of twenty inches between each pair of rows. To maintain a succession of pods, sowings should be made at regular intervals up to the last week in June. Those sown later will need protection in early autumn.

Good varieties are plentiful. I have found Sutton's Forcing an ideal variety for pot culture. The plants are very dwarf and bear a good crop of medium-sized pods of fine quality. Superlative I prefer to sow towards the end of February, when the days are getting longer. This sort and Webb's Bountiful are suitable varieties to plant for the earliest crops in the open. *Grower.*

CHRISTMAS FRUITS IN COVENT GARDEN MARKET.

THOSE who visit Covent Garden Market during the fortnight or so preceding Christmas day will find ample evidence that the festival associated with Christmas is losing nothing of its importance. Indeed, now more than ever, Christmas is a time when produce flows from all parts of the world to the great London markets for distribution throughout the length and breadth of the land. Those who have been acquainted with Covent Garden Market for the last quarter of a century are aware that the volume of trade has increased immensely during that time. Nowadays, the Market can supply choice fruits in the pink of condition, which are brought from distant lands by rapid steamships, and presented on the stands just as though they had been freshly gathered. Perhaps the greatest change that has taken place in the last decade or so is in the quantities of Apples and Pears, which may be seen in boxes and barrels sent from overseas. We are so little dependent nowadays on our own supplies of these fruits that, whether the season be good or bad, Apples and Pears of the choicest quality may be had in plenty in Covent Garden Market at Christmas time. No praise of the quality of these imported Apples and Pears can be too high, and even the Apples sent thousands of miles in barrels overseas arrive in splendid condition, while the choicest fruit in boxes are magnificent specimens. Probably the best of these imported Apples are the Oregon Newtown Pippins, and another variety of special merit is Jonathan. Of those sent in barrels there are remarkably fine fruits of Ben Davis, Northern Greening, Bismarck, and Summerfield Codlin, the last a big variety of pale yellow colour, which looks very promising for cooking purposes. The choicest of the Pears are Winter Nelis, grown and packed in the north-west States of America. The fruits are much larger than those grown in this country, and the flavour is delicious. Glou Morceau is another excellent Pear from abroad; and there are some Pears to which the name of Muskadoon is given in the Market, a very choice looking variety with a russet-brown skin. Some of the Pears are sent in barrels, the most prominent variety being Keiffer, a fruit of large size, tapering somewhat after the manner of Glou Morceau, although the whole fruit is larger.

Of our own Apples and Pears, the Market contains good samples of Bramley's Seedling, Northern Greening, Newton Wonder and Dumelow's Seedling, amongst Apples, but practically no Pears, so that the supplies from overseas will be very acceptable this Christmas.

Oranges, which are always associated with the Christmas festivities, are plentiful enough, but the choicest varieties have only just begun to arrive, the market being dependent largely at present on such sorts as Denia, Murcia and Valencia Oranges. By far the choicest Oranges are those known as Navels, from California, of which the first shipment reached this country during the past few days, and these command a very high price, retailing for about sixpence each. The Italian and Spanish Orange growers do not appear to have paid so much attention to the improvement of their varieties as have the more up-to-date American and South African growers, hence the quality of these European Oranges is comparatively poor. The Mandarin Oranges imported in fancy boxes and covered with silver or gold paper form a very attractive line, and these are sweeter than the ordinary Oranges.

Almeria Grapes packed in cork dust in barrels arrive in splendid condition, and are this year of very good quality. These cheap Grapes are in great demand at Christmas time, and a big trade is done in them. The choicer indoor Grapes are obtained largely from Holland and Belgium, but these are of very poor colour, the berries of coloured varieties being in some cases almost white. The few English Grapes obtainable are of much better quality.

Both Dates and Figs have grown considerably in importance as market fruits for Christmas time use, due to the improved methods of offering them for sale in dainty little boxes and cartons. Dates from Biskra in 10 lb. boxes, arranged so as to appear growing on the stalk, look very appetising, and find a ready sale. Thousands of small cartons are packed and sent from Marseilles, the Dates being shipped there in bulk from the French colonies. There are several brands of these dates, some much superior to others. Dates are also displayed for sale in bulk, in large boxes, in smaller boxes holding five to ten pounds, and some in narrow boxes about a yard long holding a single layer of the fruit.

Lemons do not appear to be very plentiful, but this fruit is more in demand in hot weather than in winter, although fair numbers are used at Christmas time.

The growers of Pineapples in the Azores have sent ample supplies of these choice fruits, which are realising 2s. 6d to 3s. each wholesale. The importation of Pine-apples is probably responsible for the decline in the cultivation of this choice exotic fruit in our gardens, for the price of a Pineapple grown in this country would exceed by many times the price for which the imported fruits may be purchased.

Among more uncommon fruits are Persimmons from the Rouen district of France, packed in pad baskets and small wooden boxes, realising about 4s. a box of from twelve to fifteen fruits; Mangos and Custard Apples from the Madeiras, for which there is but little demand; Cranberries from the United States, packed in boxes containing about twenty pounds; and Grape fruits from the Isle of Pines, Cuba.

FRUIT REGISTER.

APPLE KING OF TOMPKIN'S COUNTY.

I WOULD advise adding this late Apple to all plantations. In March and early April there is no variety superior to it. The fruits are of good size, highly coloured, and the tree is a prolific bearer and a good grower. I believe it is for the want of knowing the variety that it is not grown more freely. Sturmer Pippin is often recommended as one of the best late Apples, but it is not equal to the former in flavour. *W. A. C.*

HIGHLY COLOURED APPLES.

MANY times I have been requested to name the prettiest Apples, both dessert and culinary, worth growing; and in some cases, garden adornment has been the first consideration of the enquirer. Truly, no tree gives more effect to the landscape than a standard Apple tree, say, of Gascoyne's Scarlet Seedling, Devon Red or Worcester Pearmain, excepting perhaps John Downie and Dartmouth Crabs. The economic usefulness and ornamental value of these highly coloured Apples are very high. Of dessert varieties I recommend Worcester Pearmain, Barnack Beauty, Beauty of Bath, Duchess of Oldenburg, Benn's Red, Lady Sudeley, Maidstone Favourite, May Queen, Mother, St Everard, The Houblon, Wm. Crump and Wealthy. Amongst culinary sorts, with highly coloured fruits are The Queen, Peasgood's Nonesuch, Newton Wonder (this variety colours wonderfully on some soils), Mère de Ménage, Lady Henniker, Golden Noble (a rich golden yellow Apple), Gascoyne's Scarlet Seedling, Emperor Alexander, Bismarck, Annie Elizabeth and Crimson Bramley. I advise the planting of a tree or two of Worcester Pearmain on the westward of any of the varieties mentioned, to insure fertilisation of the blossom. *Pomona.*

APPLE NANNY.

IN the account of this Apple on page 354 of your issue of December 15, reference is made to *A Handbook of Fruits*, by Mr. E. A. Bunyard. It should be pointed out, however, that the Apple described under this name by Mr. Bunyard is not the true Nanny. The real Nanny is earlier in season, though in some other characteristics Bunyard's Nanny and the true variety appear to be similar. *Pip Pin.*

APPLE ALLINGTON PIPPIN.

IN the collection of the best Apples in season, shown by Messrs. Bunyard and Co. at the Royal Horticultural Society's meeting on the 11th inst., there were splendid specimens of this very free cropping variety. It may be useful to point out that Allington Pippin is one of the best of all Apples for use at Christmas, as, contrary to most varieties, this fruit improves with keeping.

WOOLLY APHIS.

THE woolly aphis, Schizoneura lanigera, is the most formidable enemy of the Apple grower. It is dangerous because its faculty of reproduction is so prodigious that it becomes a veritable scourge, because of the great difficulty in destroying it and because its ravages are so persistent that it often causes the death of a tree. The attacks of this pest if neglected, even for a short time, result in tremendous losses.

Reproduction commences in early spring, continues actively throughout the summer and, in mild seasons, into November or even December, many generations being produced during this period

Two difficulties arise in combating the pest; firstly, the insect is highly protected by the woolly substance exuded from the back of the female, which effectively resists ordinary insecticides and secondly, infestation occurs on the roots as well as on the branches and migration may take place from the trunk to the root or from the root to the trunk.

Where infestation occurs all loose bark should be removed from the trees immediately after the fall of the leaf and they should be sprayed with a caustic emulsion wash to destroy those insects which might migrate from the trunk to the root. A good wash for this purpose is made as follows:—Dissolve 1½ lb. of soft soap in 1 gallon of boiling water: add gradually 2 gallons of paraffin, churning up the whole with a syringe until it becomes a thick, creamy emulsion; stir this emulsion into 27 gallons of water in which 6 lbs. of caustic soda have previously been dissolved. In using this specific, care should be taken that the hands, face and clothes of the operator are protected.

It is not easy to attack root infestations, but where much damage is being done by the pest it is a good plan to use bisulphide of carbon. This should be injected into the soil in three or four places about two feet from the trunk of the tree at the rate of about one fluid oz. to each good-sized tree. Care should be taken that the fluid does not come into direct contact with the main roots as although the vapour is harmless the liquid is injurious.

In the spring a vigilant watch should be kept for any re-appearing insects and their attack should be pursued with redoubled energy. Spraying is not very effective because of the woolly protection of the insect and the only really efficacious way of using an insecticide is to apply it with a brush and vigorously work it in. Paraffin emulsion is useful, but needs handling by a careful person; methylated spirit is more effective.

There are not many natural enemies that do much good in checking the increase of this pest, but probably Tits are the most useful in this direction. The Blue Tit especially does inestimable good by devouring woolly aphis and other insects and should be protected in every fruit plantation. *W. Auton.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

William Carey, D.D., F.L.S.—In the biography of this great pioneer Indian missionary, which has just been published, there is a fascinating chapter entitled: "The Garden Grower." Amidst his multitudinous duties as a missionary (his Biblical translations alone were over a score) Carey found time to make great collections of plants and to found the Agri-horticultural Society of India, in 1820. At the Society's third show he could say that they were experimenting with grafts from English Apple trees, with Seville and Mozambique Oranges, with the best Mulberries and Peaches, with Cape Figs, Canton Litchis, Manilla Guavas and with the choicest Pine-apples and Vines; also with the growth of Arrowroot and Celery, Tobacco, Cotton, &c. He was a subscriber to Curtis's *Botanical Magazine*, "scarcely exceeded to-day in the glory of its colour-prints," says his biographer, who also beautifully adds: "Carey's mission work and his horticulture were twin expressions of one aim—to enrich men with God's loveliest and best." *W. Cuthbertson, Maitland Lodge, Duddingston.*

Cercidiphyllum japonicum.—There is a specimen of this pretty plant at Tyninghame about or over 30 years of age. It is not a shrub nor quite a tree, perhaps not quite 20 feet in height. Last year, Lady Holford informed me that it is the finest specimen in the United Kingdom.—*R. P. Brotherson, Tyninghame Gardens, Pestonkirk.*

——In reply to Mr. Thatcher's request for particulars of any large Cercidiphyllum japonicum growing in this country, this fine shrub does remarkably well in the South-west of Scotland. We have several plants in these gardens, the largest of which are nearly twenty feet in height, with a proportionate circumference, and although their "fleeting glory," referred to by Sir Herbert Maxwell on p. 224, is now a thing of the past, the remembrance of them when dressed in their autumn tints remains with us. Another very highly-coloured shrub in autumn is Euonymus alatus. This forms a compact-growing plant about five feet high, covered in autumn with finely tinted leaves shading from pale pink to deepest blood-red. This shrub is worthy of inclusion in any collection where autumn tints are desired. Zanthorhiza apiifolia is also beautiful in autumn when its foliage turns bronze, shading to pale yellow. It forms a dense, spreading shrub about three feet high and is useful for furnishing the front of the shrubbery border. The plant flowers in April and its curious chocolate coloured racemes of flowers, which open in advance of the development of the foliage, never fail to attract attention. *A. T. Harrison, Culzean Castle Gardens, by Maybole, Ayrshire.*

The Gloucester Root, Fruit and Grain Society.—The interesting account of the Diamond Jubilee of this Society, which appeared on page 331, recalls to my mind the financial struggles connected with its early years. My father (Mr. L. James), who is still alive, was then gardener to Wm. Nicks, Esq., Greville House, Longford, Gloucestershire, and he, accompanied by a Mr. Davis, who was then foreman at Messrs. J. C. Wheeler and Son's nursery, used to canvass for subscriptions in the evenings after their daily gardening operations. It is highly probable that many of their colleagues have passed away, but I can just remember the immense pyramidal Fuchsias that were exhibited from Greville House Gardens, the Grapes, hardy fruits berried plants in pots, and the now seldom seen Libonia floribunda. During the summer months, Messrs J. C. Wheeler and Son had a fine display of "carpet-bedding" and other plants arranged in beds, with surrounding lawns, on a piece of ground at the corner of Denmark Road. Mr. "Jack" Barnes, a local market grower, also exhibited and he, I believe, was responsible for the introduction of Adiantum gracillimum, which came up between the brickwork of a greenhouse interior. This plant was distributed by Mr. W. Bull, of Chelsea, and is now well-known to Fern lovers throughout the world. *Frank James, Allesley, Mitcham.*

Mr. W. Upjohn.—I should like to add my tribute of respect to Mr. Upjohn, of Worsley (see page 318). I was living as journeyman at a neighbouring estate, when the young men talked enviously (perhaps) of "clever young Upjohn" at Dalkeith Gardens. Mr. Thomson's eulogy of him bears out all that can be said of his professional career. After knowing him there, I met him again 25 years afterwards at the great Whit-week Shows at the Botanic Gardens, Manchester. He was always Mr. Bruce Findlay's right hand man, acting as his assistant in the arranging of the exhibits, and all who were showing could always rely on his help. I can corroborate what is written concerning the low wages of those early days. In my own case I paid a premium and received 5/- per week the first year; 6/- the second year; 8/- the third year, and after that 10/- per week, with good bothy. We had to look after ourselves, and all through the summer months we had scythe mowing from 5 a.m. until 8 a.m. and no pay for overtime or Sunday work. How different now; my son started in employment at 14/- per week as garden boy, the wage that a 40 year old foreman received 60 years ago. *Wm. Irvine (Senior), Bradley New Gardens, Grimsby.*

Rose Fanny Oppenheimer.—In regard to the note on this Rose (see page 319), it is stated that surprise was expressed by many that its merits were passed over by the judges when it was exhibited at the Autumn Show of the National Rose Society on September 20th last. It is granted that the colour of this Rose was certainly beautiful, and, moreover, it was also distinct There was all the more reason, therefore, for the judges to be particularly careful when making their decision. Its merits were very carefully weighed; so, too, were its faults. The latter, in the opinion of the majority of the judges, turned the scale. There are other things than colour to consider in a new Rose. I wonder how many of those good folks who expressed surprise at the decision of the judges took the trouble to examine the maiden plant which—in accordance with the schedule—must accompany the flowers? I think the judges made an honest award under the circumstances. The variety will, no doubt, come up again for approval, and it will again be carefully examined by the judges to see if its fault is still present. *George M. Taylor, Edinburgh.*

Schizostylis coccinea.—I agree with your correspondent *T. D. T.* (page 321) as to the merits of Schizostylis coccinea. I have grown the plant for many years. I have plants in six 10 inch pots and up to the time of writing I have cut over four dozen spikes and as many more remain for cutting. The plants flower from the beginning of November to the end of January. I divide and repot the plants in April, standing them out-of-doors, near Chrysanthemums, and giving them similar treatment. They are brought into a cool house in the first week of October I have crossed this Schizostylis with Montbretia Star of the East and have 100 seedlings in a cold frame just showing signs of pushing up their flower spikes. I hope to flower these plants in the frame. I shall be pleased to write you the results at a later date. *W. Turner, Winthorpe House Gardens, Newark.*

SOCIETIES.

SMITHFIELD CLUB.

THE Cattle Show at Islington is one of those seasonal events that have a special interest for the country dweller, and horticulturists as well as agriculturists always find much that is of interest at this great metropolitan show of cattle, sheep, pigs and poultry, for in addition to the animals and birds, exhibits of a miscellaneous character, that are staged in the gallery and the Gilbey Hall, provide an opportunity for the rural worker to become acquainted with the latest appliances and sundries pertaining to rural industries. Thus the farmer has brought prominently before his notice the latest types of farm machinery, including tractors, ploughs and reapers, fencing, binding material, dairy implements, covers, sacks, elevators pumps, agricultural tools and a thousand and one other things that are used on the farm.

The horticulturist also uses many of the things displayed at the Cattle show and he finds, beside such things as barrows, bags, baskets, tools, ropes, lines, cords, insecticides, fungicides, fertilisers, etc., many interesting and useful things among the implements, such as small cultivators, manure distributors, Potato-lifters, oil-driven engines, pumps, trucks, spraying and lime-washing machines. The gardener also finds displays of seeds of vegetables that are of special value for cultivating on a large scale to obtain produce of the kind required by market gardeners and farmers. Many noted seed houses had exhibits of farm and garden seeds at the recent show, the latter principally of the special type to which we refer.

Messrs. SUTTON AND SONS had one of the largest exhibits of this kind in the gallery and the display took the usual form of a collection of large roots, such as Mangolds, Swedes and Turnips interspersed with cereals, fodder plants and numbers of choice vegetables. Of the farm roots they showed a new Mangold which has not yet been named, of the Globe type, deep in colour, with a solid flesh of high feeding value. They also had a very fine new Swede, said to be far in advance of anything in commerce for feeding qualities and for its hardiness. Their exhibit contained some of the finest Swedes in the Show. The vegetables included some thirty varieties of Potatos, embracing all the newer varieties, and it was interesting to note that the dish of Up-to-Date variety was of almost perfect quality and from appearance still equal to any variety shown. They had also splendid Onions of the selected Ailsa Craig type, Exhibition Sprouts, excellent Leeks of the Prizetaker variety, Stachys tuberifera, Carrots, Tomatos, Celeriac, Turnips and many more.

Messrs. JAMES CARTER AND CO. also had a big exhibit arranged in a somewhat similar manner in which Mangolds, Swedes and Turnips were prominent features. The roots of Model Kohl Rabi were as large as some of the Mangolds, and it was interesting to note the great difference of the size of the Kohl Rabi in the collection of garden vegetables, the latter being no larger than tennis balls. This firm showed many varieties of Peas, amongst which we noticed such old favourites as Harrison's Glory, Thomas Laxton, Senator and Standard, whilst of Broad Beans there was a fine sample of the White Leviathan sort; excellent Potatos, a very fine Purple-topped Yellow Turnip, Autumn Queen Onions, Carrots and other roots, were included in this exhibit.

Messrs. J. KING AND SONS were also the exhibitors of large farm roots and in addition we noticed some splendid dishes of Lord of the Isles and King John Potatos, varieties that are not so extensively known as some others. Their Reading Matchless and Exhibition Globe Onions were of very high merit

Messrs. E. WEBB AND SONS had an exhibit of large extent in which they displayed Mangolds, Swedes and Turnips for farm purposes and

Digitized by Google

also a number of vegetables for garden purposes. The latter included the second early Potato Mighty Atom, which has an exceedingly russety skin, and also a new sort named Ardneil Rose, an early variety with somewhat deep eyes. They had also excellent Beet of the Volunteer variety, large Onions of Ailsa Craig and Webb's Masterpiece, Carrot Defiance Intermediate, and Leeks Champion Prize, their vegetables being some of the finest in the exhibition.

Other exhibits of this nature were shown by Messrs. TILLIE-WHITE AND CO., Messrs. ALEX. BLATCHFORD, LTD., Messrs. CANNELLS, Messrs. GARTONS, Mr. H. J. SPEED, Messrs. KENT AND BRYDON, LTD., Messrs. TOOGOOD AND SONS, Messrs. E. W. KING AND CO., Messss. W. DENNIS AND SONS, Messrs. HARRISON AND SONS, and Messrs. DICKSONS, LTD.

Large numbers of growers of Potatos for seed purposes had samples on view, but the majority displayed only ware tubers. In our opinion the prospective purchaser of seed tubers would have been more interested in samples fit for planting, although this year the majority of seed Potatos are on the large size, and in some cases we were informed that certain varieties have failed to produce tubers of seed size at all. Amongst the varieties of Potatos, Field Marshal, which is not immune to wart disease, impressed us by its appearance, and although it has a considerable amount of russet as in Golden Wonder, the popular belief that it is a cross between Golden Wonder and Up-to-Date is said to be erroneous. It is, however, a fine-looking Potato and said to be a heavy cropper. Mr. T. A. SCARLETT, Edinburgh, was one of the few Potato exhibitors who showed other things in addition to Potatos; he had some remarkable fine bushes of the new Edina Black Currant and very large heads of Ormskirk Savoys.

The only exhibitors of fruit were Messrs. SEABROOK AND SONS, who showed finely coloured Apples of such sorts as Bismarck, Rival, Wealthy and King of the Pippins; some of the fruits were packed in market boxes.

THE ORCHID CLUB.

DECEMBER 14.—The first meeting of the newly established Orchid Club at Manchester, was remarkable for the large number and fine quality of the Odontoglossums and Cypripediums shown. At 3 o'clock Professor W. H. LANG F.R.S. gave a short address on "The Bird's Nest Orchid" as exemplifying in the most typical way, the important commensalism which obtains between the Orchid and its associated fungus, and discussed the work which had already been done on the substitution of special nutrition for fungous action in the early stages of Orchid development.

AWARD

PREMIER DIPLOMA.

Cypripedium Chrysostom, var. Richard Fort. (Christopher var. Grand Duke Nicholas - Pyramus magnificum), a large flower, the dorsal sepal, 4½ inches in diameter, is flat and well displayed; it is white with a small green luna and purple spots radiating on to the white ground. The petals and lip are in good proportion, well displayed and in colour greenish yellow tinged with mahogany-red.

GROUPS.

Mr. FRED HARDY, Ashton-on-Mersey (gr. Mr. C. Branch), exhibited a group of exceedingly well-grown Odontoglossums carrying full spikes, and including sixteen members of the xanthotes section and eight coloured forms, amongst which Hardyanum, with a spike of fifteen flowers, was remarkable for the substance, size, perfect form and colouring of the flowers. A new Odontioda hybrid, with only four flowers of the spike open, was of superlative excellence.

Mr. G. F. MOORE, Bourton-on-the-Water (gr. Mr. W. H. Page), exhibited a small group of the new Chardwar hybrid Cypripediums, including the varieties Mrs. Eley, Chrysostum var. Grace Darling, Our Prince, The Great Mogul, W. H. Page, Memoria F. M. Ogilvie vars., Conyngham and Premier. Mr. Moore also showed cut blooms of C. Chrysostom, Chardwar var., C. Gwen Hannen, Chardwar var., and C. Prince Albert, Chardwar var., all of which were awarded the R.H.S. F.C.C. on the 11th inst.

Mr. B. J. BECKTON, Irlams o' th' Height (gr. Mr. W. A. Stewart), exhibited a large collection of mixed Orchids; the centre of the group consisted of Coelogyne barbata with plants of Laelia Gouldiana and Epidendrum vitellinum. The exhibit also contained well-grown Cypripediums and finely-grown plants of Oncidium corynophorum.

Dr. F. CRAVEN MOORE, Manchester, exhibited a selection of Cypripediums, including C. Madame Albert Fevrier var. Oxford, a fine form of C. Charlotte Dillon, C. Corsair Holford's variety, and C. Monialis.

Mr. A. T. CUSSONS, Haliwell House, Kersal, (gr. Mr. F. Cookson), staged a group of Cypripediums, a good plant of Trichosma suavis and other Orchids.

Dr. HARTLEY, Wigan, had an effective group in which Cypripedium John Hartley, fine forms of Oncidium Forbesii and well-flowered plants of Platyclinis Cobbianum were conspicuous.

Hon. H. D. MCLAREN, Bodnant (gr. Mr. F. C. Puddle), showed several interesting plants, including a good form of the beautiful new Cypripedium Albion.

Sir WILLIAM THOM, Athol House, Blackburn, staged a few choice Cypripediums, including C. burtonense and a pretty variety of C. Sanaederae.

Mr. J. H. WALKER, Oak Cottage, Eccles (gr Mr. C. Weaver), exhibited a fine group of Cypripediums, among which various varieties of C. Maudiae were conspicuous.

Messrs. JAMES CYPHER AND SONS, Cheltenham, showed a large and effectively arranged group, comprising many well-known varieties of Cypripediums, Cattleya Astion, Oncidiums and well flowered plants of Masdevallia tovarensis.

ROYAL CALEDONIAN HORTICULTURAL.

DECEMBER 4.—The ordinary monthly meeting of this Society was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. W. G. Pirie, vice-president, in the chair. Professor W. Wright Smith, Royal Botanic Garden, Edinburgh, delivered a lecture entitled "Life in a Tropical Garden," which was illustrated by lantern slides. The garden described was the Calcutta Botanic Garden, which, as Professor Smith remarked, had been under the direction of Scotsmen since its foundation by Colonel Kidd in 1785.

The exhibits were:—Chrysanthemums, from Messrs. DOBBIE AND CO., Edinburgh; Primula malacoides and P. m. alba, from Mr. D. ARMSTRONG, The Drum Gardens, Edinburgh (awarded a Cultural Certificate); and Primula malacoides Pink Beauty, and Ornithogalum thyrsoides (Chinkerichee), from Mr. ARNOT, Corstorphine. The intimation was made that the Society would hold a Spring Flower Show on the 11th and 12th of April, 1924.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE monthly meeting of this Society was held in the R.H.S. Hall on Monday, December 10, Mr. T. R. Butler presiding. Three new members were elected. Two lapsed members withdrew the sum of £17 12s. 3d., and two members over 70 years withdrew £3 from their deposit accounts. The sick pay on the private side amounted to £75 10s. 8d. and on the State section to £68 18s. 6d., while maternity benefits totalled £12. Grants for extra benefits were made to five members and amounted to £10 12s. 9d.

TRADE NOTES.

THE Ministry of Agriculture has deemed it necessary in the early part of 1923 to issue an Order (The Colorado Beetle Order of 1922) which in effect prohibited the entry into this country of living plants and vegetables grown in a wide area in France. Following representations made to the Ministry, it has now been decided to amend the regulations. The Colorado Beetle Order of 1923 has accordingly been issued and this came into operation on the 17th December 1923, revoking the corresponding Order of 1922.

The effect of this new Order will be that in place of the declaration required at present, each consignment of living plants, Potatos or Tomatos shipped from ports in European France to this country must in future be accompanied by the under-mentioned certificate or copy certificates:—

(1) If grown in France.

(a) For Potatos and for all plants which are subject to the Destructive Insects and Pests Order of 1922, the copy certificates required under that Order. These certificates must be officially endorsed to the effect that the produce was not grown in the neighbourhood of those districts where the Colorado Beetle has existed.

(b) For Tomatos and for plants which are not subject to the Destructive Insects and Pest Order of 1922, an official certificate to the effect that the produce was not grown in the neighbourhood of those districts where Colorado Beetle has existed.

Either the copy certificates required under the Destructive Insects and Pests Order of 1922, or a certificate of origin viséd by a local authority in the country of origin; the country and the place where the produce was grown must be stated in the certificates

In all cases, the relative certificate or copy certificate must be delivered to an Officer of Customs at the same time and together with the entry relating to the consignment. In the event of failure to produce the necessary document, a consignment must be destroyed or re-exported by and at the expense of the importer unless its disposal is otherwise authorised by the Ministry.

It will be noted that in future no certificate or declaration of any kind will be required in the case of vegetables for consumption other than Potatos or Tomatos.

Obituary.

John Jaques.—We regret to learn that Mr. John Jaques died at Grey Friars, Chorley Wood, on the 17th inst, after a long illness. He was in his 82nd year, and for many years previous to his retirement was gardener to the late Miss Alice de Rothschild, at Waddesdon Manor, Aylesbury.

W. H. L. Laxton.—We very greatly regret to learn of the death of Mr. W. H. L. Laxton, which occurred on the 14th inst. after a brief illness. The deceased gentleman was senior member of the firm of Messrs. Laxton Bros., Bedford, and for the past thirty-five years he had been engaged in the interesting business of raising new varieties of fruits, notably Apples and Strawberries and new culinary Peas, and the successes he and his brother, Mr. E. A. Laxton, have achieved are well-known in the horticultural world. Mr. W. H. L. Laxton was fifty-seven years of age. After education at Bedford Modern School he proceeded to Germany and was with Messrs. Haage and Schmidt for some time. On returning to England he entered the service of Messrs. Jackman and Sons, of Woking, to obtain a wider knowledge of the nursery trade. Subsequently he returned to Bedford and eventually became partner in the firm of Messrs. Laxton Bros. He had not enjoyed very robust health for a long period, but was nevertheless a frequent visitor to the principal horticultural exhibitions in London and the provinces and was a well-known member of the horticultural trade.

ANSWERS TO CORRESPONDENTS.

BLACK CURRANT SHOOTS: *H. P. K.* The specimens sent are, as you suspect, affected with Big Bud mite. If the whole plants are very badly affected, your best plan will be to cut down the bushes and burn them on the garden fire The plants will send up strong sucker growths and fruit again in a year or two. If the numbers of big buds, however, are not very numerous, remove the swollen ones by hand-picking, taking care not to allow them to fall on the ground, and burn them. In late spring and early summer the bushes should be dusted with lime and sulphur, one part of finely-ground quicklime and two parts of sulphur, and again on two occasions at intervals of a fortnight.

CHRYSANTHEMUM BUDS FAILING TO OPEN: *Mayflower.* The trouble is not due to disease. In the immediate neighbourhood of London this trouble is not uncommon in the case of late varieties, and is doubtless due to lack of light. In your case the trouble may be caused by lack of sunshine during the autumn, as the shoots appear too soft and unripened. Overfeeding, combined with lack of sunshine, might also cause the flower buds to become abortive.

MOSSES IN FLOWER POTS: *G. C.* Sample No. 1 consists largely of Mosses, a species of Polytrichum being numerous; and Sagina procumbens, a flowering plant. No. 2 consists chiefly of Marchantia polymorpha with cup-like structures, and apparently a few bits of Lunularia with half cups, all containing bulbils or gemmae which reproduce the plants. Both these belong to the Marchantaceae, allied to the Mosses. No. 3 consists chiefly of Mosses of the Hypnum and Polytrichum types in the young stage with an occasional grass. The soil is very heavy and contains little vegetable matter. It is useful for Vines and Roses because it will hold artificial fertilisers well. It is well mixed with coarse silver sand, but may have been rather sour when first obtained, and this favours the growth of Mosses, these being often the first vegetation to grow upon sour soil. There are two methods of dealing with the Mosses Marchantia and Sagina. In winter the soil may be allowed to become fairly dry, when it should be well scratched with a label or pointed stick, and the bulk of the Moss taken off by hand on wet days. A boy could be set to do this. Another plan is of a preventive nature, and consists in putting a peck, more or less, of quicklime in a barrel of water and letting it stand for twenty-four hours. The pots should then be watered with the clear liquid which will sweeten the soil and render it less suitable for the growth of Mosses. There is no fear of using it too strong, because the water will not hold more than a certain amount of lime. The plan of scratching the surface soil is often adopted by gardeners, because the Mosses wither and die off when the pots are left dry for two or three days.

POTTING PALMS: *M. T.* Although the present is not a good time for re-potting Palms, there is no reason why your plants should show signs of distress, assuming the work was carefully done. But Palms, especially old ones, resent much interference with their roots, as they are very apt to die back if unduly disturbed; and once they get into the condition you describe it is not easy to bring them back to health again. The best plan is—if possible—to put them in a warm house, where a close, moist atmosphere is maintained, taking special care in watering until they have made new roots. The best compost for Palms is a good fibrous loam, with about one-third leaf soil and some clean, coarse sand to keep the whole open and porous. Palms should always be potted fairly firmly.

REMARKS.—This department is getting very busy and a further rise in prices is anticipated, especially for Carnations and Roses. There is likely to be a very limited supply of the latter flowers; Scarlet Carnations will also be in great demand and no doubt will realise high prices before the market closes on Saturday next. There is the usual big demand for Chrysanthemums, both white and coloured, in disbudded blooms and "spray" in bunches; the quality of Chrysanthemums generally is fairly good, and according to present consignments there will be sufficient for all requirements, with a slight advance in prices. It is difficult to give correct quotations for Liliums and Richardias (Arums); at present there is every prospect of there being good supplies of these flowers as well as of Lily-of-the-Valley. Cut Roman Hyacinths appear to be fairly plentiful, also white Camellias. Poinsettias are usually in great demand during the week previous to Christmas, but this year supplies promise to be cut very short before the week-end. French flowers include Narcissus Paper White and Soliel d'Or, Acacia (Mimosa), Anemones, scarlet Ranunculus and Violets. White Lilac, of which there is likely to be a good supply, will be in good demand. The best berried Holly is arriving from France this season and meets with a good demand. Large consignments of Mistleto are expected for this week; already large quantities have arrived and been despatched to Scotland and provincial English towns. There have been large quantities of Picea and other Conifers used as "Christmas Trees," and they have sold freely at reasonable prices.

REMARKS.—The seasonable demand has caused some expansion in the volume of business and in many sections improved prices are recorded. Ample stocks of Apples from the North American continent are on offer and quotations are firmer. More English Apples have been marketed lately but prices have been maintained for really first grade consignments. English Cox's Orange Pippins are scarce and all supplies meet a ready sale. Grapes are moderately plentiful and in much demand just now. Pineapples also are selling well, two timely shipments meeting a good market. Oranges from Spain are plentiful and cheap, although not yet of very good quality. Bananas meet a steady trade, as do the various fruits from Madeira. Forced Asparagus shows an improving tendency after a very bad period. Forced Beans, although inclined to be easier in price, are still comparatively costly. New Potatos are inquired for, especially hothouse grown produce. Mushrooms are plentiful and are offered at lower prices, which is not unusual at this season of the year. Beans from Madeira have cleared readily at higher prices. Brussels Sprouts are in better demand and the Potato trade shows some improvement.

CATALOGUES RECEIVED.

The Inheritance of Immunity to Wart Disease.

THE mode of inheritance of immunity to Wart Disease exhibited by varieties of Potato is a subject of the greatest interest both to the grower and the man of science. The grower, particularly if his land is situated in an "infested area," is interested for many reasons, but chiefly because of the announcement which is made from time to time that in such a variety immunity has broken down and the variety has become susceptible to the disease. The careful and thorough investigations which have been carried out by Dr. Salamon and Mr. Lesley during the past ten years, the results of which have been recently published,* may serve to reassure Potato growers as to the permanence of immunity in Wart-disease resisting varieties. Immune varieties kept under observation for ten years and even longer—in the case of Sutton's Abundance for fourteen years—have maintained their immunity intact. As the author points out, the occasional reports to the contrary are probably due to the chance introduction of susceptible rogues into immune stock. That the Ormskirk trials are thorough may be judged from the facts that the number of plants of a variety which is grown in the immunity trials is forty and the trial extends over two years. The latter provision is necessary for, even in soil thoroughly infected with the Wart Disease organisms (Synchytrium endobioticum), the disease may fail to declare itself in a variety if the season is unfavourable for the infection of the tubers by the parasite. Thus, in a dry season, susceptible varieties may escape not only because moisture favours infection, but also because in such seasons the tubers ripen rapidly, and hence tend, as it were, to run away from infection. The results of breeding experiments carried out by Messrs. Salamon and Lesley give yet firmer support for the view that immunity is a fixed character. These results show that immune varieties self-fertilised or crossed with another generally give rise to a large number of immune and a small number of susceptible offspring. On the contrary susceptible varieties selfed or crossed with one another produce offspring of which either all or almost all are susceptible. These facts indicate that immunity is what is known as a dominant character dependent on the presence in the germ cells of one or more factors which prevent the tubers from becoming infected. As an example, the result of crossing the two immune varieties, Kerr's Pink and Champion II, may be cited. The number of seedlings tested was seventy-nine, and of this number seventy-six proved immune and three susceptible. On the other hand, crosses between the two susceptible varieties, Myatt's Ashleaf and Edgecote Purple, gave one-hundred-and-fifty-one seedlings, of which one-hundred-and-twenty-two proved to be susceptible and only twenty-four failed to become infected. Students of genetics who scrutinise these and other results obtained by the authors will agree with the suggestion put forward by Messrs. Salamon and Lesley that immunity depends not on a single factor but on two, or it may be more than two, factors. The nature of the two factors for immunity remains unknown, and for purposes of description the factors may be denoted by the letters X and Y. From the results of the numerous experiments which have been made in which different immune varieties have been used in breeding, it is to be inferred that the presence of either factor confers immunity. A variety which possesses *one* of the immunity factors even though it lacks the other is, nevertheless, immune. It follows, therefore, that the immune varieties in existence fall into different categories. All have at least one of the factors, but some have both. Some, moreover, having inherited both factors from both parents, have these factors in double dose. Other have more mixed genetic compositions. Thus, immune varieties form a series of different genetic composition and, hence, will give different numerical ratios of immune and susceptible offspring when selfed or crossed with one another. Without pursuing this analysis further, the satisfactory conclusion may be emphasised that whether an immune variety be genetically pure or impure for the immunity factors, its tubers may be expected to continue always to retain their immunity. The inheritance of immunity may, however, be more complicated than this simple scheme would suggest. The authors find that some immunes when selfed, *e.g.*, Leinster Wonder, give immunes and susceptibles in proportions which cannot be explained by the two-factor hypothesis, and they are driven to assume that in this case, and probably in all cases, there is a third party to immunity—a third factor, Z, which must be present for either X or Y to exercise its immunising function. In many immune varieties Z is present, and if two such varieties are crossed there will be no indication that this factor is exercising its beneficent work; but from some varieties the third (Z) factor is absent, and if a cross be made of one of such varieties with another variety which contains Z, only the offspring in which X and Z or Y and Z are present will behave as immunes. Yet another complication is introduced by the behaviour of the well-known Myatt's Ashleaf. Although susceptible, this variety when self-fertilised gives susceptibles and immunes in almost equal proportions, and the conclusion is forced upon us that Myatt's Ashleaf is really an immune variety in which the factors for immunity which it contains are rendered impotent to prevent infection because of some other factor which prevents the immunity factors from exercising their effect. Cases of such inhibitors are well known. Certain white Primula sinensis flowers have been shown to owe their whiteness, not to a lack of the factors for colour, but because they possess a factor inhibiting the development of flower colour. From these experiments, which deserve to be studied with attention by all horticulturists, we have a new and more vivid picture of the nature of susceptibility and immunity. Certain varieties are lacking in all the immunity factors and fall ready victims to Wart Disease; others may have an immunity factor but, containing also an inhibitor, though they may put up a good resistance, such varieties in the end fall victims to the disease. Others, though they are susceptible, may contribute, when crossed with immunes, to the immunity of the offspring. Lastly, any variety which proves its immunity in the field may have one of many genetic constitutes and, accordingly, may be more or less propitious as a starting point for the breeding of new immune varieties. Above all, these observations are of the utmost importance to all breeders of varieties, and we recommend to them the most careful study of this most important research.

* "Genetic Studies in Potatos: The Inheritance of Immunity to Wart Disease." By R. N. Salamon, M.A., M.D., and J. W. Lesley, M.A. *Journal of Genetics*. 13, 2nd August, 1923.

"Gardeners' Chronicle" Almanack for 1924.—We shall publish in our issue of January 12 a "Gardeners' Chronicle" Almanack for the year 1924. In order to make it as useful as possible for reference we shall be obliged if Secretaries of Horticultural, Botanical, and Allied Societies, or any of our correspondents WILL SEND US IMMEDIATE INFORMATION OF ALL FIXTURES FOR THE ENSUING YEAR,

A Gardeners' Library in the City of London.—In 1891 the Worshipful Company of Gardeners started a gardeners' library with just over one hundred books on gardening; with these books as a foundation the Gardeners' Company is now getting together a fine library for the free use of professional and amateur gardeners, horticultural students and such of the general public as may be keen lovers of gardens as well as admirers of flowers. At the instance of the Company's Master, Mr. Victor Brown, some £120 has already been subscribed by certain of the members to enable the Guildhall Librarian to begin the purchase of the best books on every horticultural subject, so that what is at present often beyond the reach of the average reader may be easily consulted in the library. These books are to be placed in a large case in the Newspaper Room at the Guildhall Library, London, E.C. 2, where they will be seen by hundreds of readers daily, and should form the nucleus of a large and valuable library. If the Gardeners' Company can obtain the practical sympathy of the general public, as well as of its own members, a library of national horticultural importance may be

Digitized by Google

established in the heart of the City of London. Any questions and suggestions regarding the scheme may be addressed to the Clerk of the Gardeners' Company, Mr. E. A. Ebblewhite, 5, Essex Court, Temple, London, E.C. 4.

Magnolia virginiana × M. macrophylla.—According to *Bulletin* 12 of the Arnold Arboretum there is in North America no more satisfactory shrub or tree for garden planting than Magnolia virginiana. It bears dark green lustrous leaves, silvery-white below, and though its flowers are smaller than those of other North American species they are beautiful and fragrant, and moreover open from June to August when danger of late frosts is past. The hybrid, M. Thompsoniana (M. major) has larger leaves and flowers, the latter with evening perfume as pleasingly fragrant as that of M. virginiana. This hybrid has for its parents M. virginiana and the Umbrella tree, M. tripetala. The last of the Magnolias to flower in the Arboretum is M. macrophylla, which, though a native of the southern States, is hardy in Massachusetts, where it may reach a height of thirty feet. It has the distinction of possessing the largest leaves and flowers of any tree outside the tropics. The leaves, silvery white on their lower surfaces, are from twenty to thirty inches in length and eight to nine inches in breadth, and the expanded flowers are often a foot in diameter. Though hardy at Boston it is found best to plant M. macrophylla in a position in which it is sheltered from the wind, as otherwise its large and delicate leaves are apt to be badly torn.

Visit of H.M. the Queen to Kew.—Her Majesty, Queen Mary, recently visited Kew for the purpose of planting a tree on the site of the Temple of the Sun, which was destroyed by a Cedar of Lebanon crashing on it during a gale in March, 1916. The object in planting the tree is recorded by the following notice placed by the side of the tree:—"Maidenhair Tree. Ginkgo biloba. This tree was planted here on the site of the Temple of the Sun by Her Majesty the Queen on November 27th, 1923. The Temple of the Sun, which was destroyed in the gale of March 1916, marked the centre of the original Botanic Garden established by Princess Augusta, Princess of Wales in 1760. The fine Maidenhair Tree close by was probably planted by Princess Augusta about 1762."

Dr. L. Cockayne, F.R.S.—The Canterbury Philosophical Institute, which is one of the affiliated societies of the New Zealand Institute, has honoured itself as well as the recipient by electing Dr. Leonard Cockayne, F.R.S., to honorary membership. It is notable that this is the first occasion since the formation of the society in 1868 that an honorary member has been elected. Naturally Dr. Cockayne, who is an old worker and officer of the Institute felt gratified at the honour; his friends are equally gratified, and trust that his energy and enthusiasm in field work and in transferring the result of his field work to print may continue. Dr. Cockayne joined the Canterbury Philosophical Institute in 1895, and was elected to its presidency in 1899. He read his first paper "Improvement of wild flowers by artificial selection" in 1896, followed in 1897 by a paper describing experiments with Alpine plants in a freezing chamber; this was his first paper published in the *Transactions of the New Zealand Institute*. Since that time nearly every volume has contained some of his work. In addition he has prepared valuable departmental reports on botanical subjects, in the preparation of which he has visited almost every part of New Zealand and its outlying Islands. He has also found time to publish two books. *New Zealand Plants and Their Story*, issued in New Zealand, is now in its second edition; *The Vegetation of New Zealand* has passed through one edition, and a revised edition is now being prepared. He also has in the press a hand-book on the *Culture of New Zealand Plants*.

Mr. A. J. Ward.—Mr. A. J. WARD, Superintendent of Shrewsbury public parks comes from a family of gardeners. His father was superintendent of the Norwich City Parks for many years, and previously gardener and forester to the late Lord Dunleath, and it was under his father that Mr Ward received his early training in gardening. He secured an appointment as improver in the gardens at Battenhall Mount, the residence of the Hon. Percy Allsopp. Leaving there he served as a journeyman in Welbeck Abbey Gardens. From there he went to the Royal Gardens, Windsor Castle, and gained considerable knowledge under Mr. MacKellar. At Windsor he had charge of the Palm house, conservatory, etc., and also took a leading part in arranging the floral decorations in the castle. His next appointment was as floral decorator to the late Mrs. Bischoffsheim at Bute House, London, whose house parties often included members of the Royal Family. Mr. Ward next turned his attention to public gardening

MR. A. J. WARD.

and served under his father in the Norwich City Parks, leaving there to take up a more responsible position in the Birmingham City Parks under Mr. W. H. Morter, the Chief Officer. During his six years service as foreman he gained a first class knowledge of the upkeep of public parks, gardens, playing fields, etc. He was appointed to his present charge in March, 1914, and has given the utmost satisfaction to the Shrewsbury Corporation and townspeople. The beautiful Quarry Park, where the great Shrewsbury flower show is held, is probably known to more gardeners than any other public park in the country, and has been greatly improved during Mr. Ward's term of office. Thanks to the generosity of the Shropshire Horticultural Society, this year he has been able to continue the improvements, which were admired by visitors at the recent show. Mr. Ward has gained the confidence of all under whom he has served and is held in the highest esteem in horticultural circles in Shropshire.

A Gardener's Successful Efforts on Behalf of the two Gardening Charities.—Mr. W. Auton, of Pyrford Court Gardens, Woking, has raised the sum of £62 for the two gardening charities, the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund, and the amount has been allotted equally between the two funds. It will be remembered that last year Mr. Auton was successful in raising the sum of £42 (see *Gard. Chron.*, January 27, 1923, p. 44), and his method of obtaining this considerable sum may be of interest to other gardeners who might desire to help these two deserving institutions. A whist drive was promoted on October 11 to raise money to finance a greater scheme held in December. The whist drive resulted in a profit of six guineas. During the time between the whist drive and December 12, Mr. Auton arranged for the collection of material for a rummage sale and sale of garden produce. This was responded to very liberally by residents in the Pyrford district, and most owners and gardeners of both large and small gardens contributed plants, flowers and vegetables for the garden produce stall. The sales were held in the afternoon of December 12 and they were followed by a fancy dress ball in the evening at which over one hundred people attended, the dance alone showing a profit of nearly £10. An interesting fact in connection with the fancy dress ball was that the first prize for a lady's fancy dress was awarded to a costume made up of Messrs. Carter and Co.'s seed packets, the wearer carrying a basket of vegetables to represent the produce. Doubtless there are many other districts where money could be raised in such a manner, and it is to be hoped that other gardeners will adopt similar methods to those of Mr. Auton to assist the good work which is being done by both the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

Germination in Light and Darkness.—From experiments carried out by Mr. G. Wieringa and reported in the *Seed World*,* it appears that certain garden seeds give equally good results when tested for germination capacity in light or in darkness; but that others give better results when the test is carried on in the light. To the former category belong Parsnip, Chicory and Parsley, and to the latter, Tomatos, Celery and Endive.

Professor of Horticulture and Pomology for Sofia.—The University of Sofia is inviting applications for the appointment of a Professor of Horticulture and Pomology. The engagement will be for five years, but if the selected candidate acquires Bulgarian nationality, it will be renewable indefinitely. During the first two years lectures may be given in any Slavonic language, French, or German, but after the expiration of two years they must be given in Bulgarian. Applications should reach the Rector of the University of Sofia not later than January 31, 1924. Further information concerning the Professorship may be obtained from the Ministry of Agriculture and Fisheries, 10, Whitehall Place, S.W. 1.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Orchids at the Horticultural Society's Garden.*—We have on former occasions stated that Mr. Gordon has been treating the Orchids under his care on a different plan from that generally followed. Instead of keeping them uniformly warm and moist, he pursues the opposite course of keeping them comparatively dry and cool, more especially in winter, so as to give them a season of complete repose. The result of this treatment is that the plants awaken on the first excitement in spring with fresh vigour, make excellent growths early, which become well ripened by autumn, and the plants are again allowed to go quietly to rest. Under this system of management they have so much increased in size that they will soon require more ample accommodation than the present Orchid-house affords them. The broad, healthy foliage, extending across the pathways from their opposite sides, already precludes the possibility of walking comfortably along them. The finely-flowered specimen of Barkeria Skinneri, which was exhibited at the last meeting in Regent Street, is still in perfection, and promises to continue so for some time to come. Phalaenopsis amabilis, which flowers nearly all the year round, was also finely in blossom. *Gard. Chron.*, *December* 23, 1848.

NOTICE OF BOOKS.

Apple Culture in America*.

It is always interesting to read about the methods of fruit culture adopted in other countries. In this little book the author, who is qualified by both practical experience on his own farm and by theoretical training, sets out to help general farmers in the North-eastern States to make the fruit department more profitable. It appears that the "wasted orchard" is almost as common an object on American farms as it is in this country, for we are shown that the production of Apples in the United States has steadily declined in the last fifteen years, owing to the decay and destruction of old trees, and this in spite of the heavy planting in recent years.

In many respects American cultural methods do not differ from our own, but in some directions there are marked contrasts. Here we choose a mild aspect for an orchard where possible, but this author advises planting the Apple on the colder slopes, which hold it back in spring until danger from frost is past, north-east exposures being considered best. Trees with stems from 3 feet to 4 feet high are favoured; and these evidently grow to enormous size, since they are expected eventually to fill the space when planted from 35 feet to 40 feet apart. To bring in an early return "fillers" are often planted temporarily between the permanent trees, these having stems 18 inches high. Peaches and Japanese Plums may be used for this purpose in favourable localities, and Pears and European Plums in colder districts. Further intercropping with farm crops or vegetables is also advised in the young orchard, but no mention is made of an under-crop of bush fruits or Strawberries such as is popular in this country. Pruning is not treated at all fully, but it appears to be much lighter than is common with us.

Cultivation plays an important part. When the orchard has grown beyond intercropping it is usually ploughed in early spring, cultivated repeatedly up to midsummer to get a tilth, after which shallower cultivation with lighter implements is continued to maintain a dust mulch in a dry season. In July or August the land is sown with a cover crop, to be ploughed in during the following early spring. The use of Leguminous crops for this purpose supplies the orchard with the necessary organic nitrogen, the other plant foods being given in the form of mineral fertilisers Grass orchards are grazed with sheep or pigs, the latter preferred, but they are considered to be inferior to cultivated orchards. The "sod mulch" system, however, is recommended for hilly land where cultivation is difficult, and for districts with a heavy rainfall. A regular routine of spraying is prescribed, and is much on the lines recommended in this country. Marketing systems and problems are almost identical with our own.

THE ROSE GARDEN.

ROSE DR. A. J. PETYT.

Of the many new Roses of recent years there are few, to my mind, that stand out so prominently as the variety Dr. A. J. Petyt. The colour is a dark crimson, shaded maroon; the blooms are of perfect shape, with large, massive petals, and are very freely produced on strong, upright stems; moreover, they are very sweetly scented. It is a particularly desirable Rose and one that is suitable alike for exhibition and garden cultivation, and ideal for bedding. I have had it for some two years in my garden and am very pleased indeed with it. It is a seedling from George Dickson with all that excellent Rose's good qualities and none of its bad ones. Messrs. Burrell and Co. are to be congratulated on this fine production. *C. P.*

* *Apple Growing.* By M. C. Burritt. The Macmillan Company. pp. 177. Price 4s. 6d. net.

TREES AND SHRUBS.

VERONICA SALICIFOLIA.

I was pleased to learn from Mr. Richardson's note on p. 309, that the above species of shrubby Veronica has proved so hardy at Edinburgh, even although I knew that the Maiden Town has long been a home for the shrubby Veronicas in this country.

Mr. George Nicholson had and Mr. W. Bean has ample opportunity of knowing that V. salicifolia cannot be regarded as hardy at Kew. Very few of the fine collection came safely through the winter of 1916-17, for the long border has been almost completely replanted since then. The same species has, however, been repeatedly planted at Kew during the past forty years, only to be killed during severe winters. The soil is a very sandy alluvium. Two fine plants of V. salicifolia growing in a clay soil in mid-Surrey, three and five feet high respectively, flowered handsomely previous to the severe winter referred to above. The largest plants I know at present are at Merstham, Surrey, on the gault formation, and they flower profusely all the summer long, as stated by Mr. Richardson, and are six to seven feet across each way so near as I can remember. It was my impression that soil has something to do with the hardiness of this Veronica. I have also seen it sowing itself freely in a Berkshire garden, and a seedling I obtained from there was killed by frost after it had lived for three years. I may also refer to V. lobelioides (V. elliptica × V. speciosa) raised by Mr. J. A. Henry of Edinburgh in 1862. I compute that thousands of plants of this Veronica were killed in the above severe winter in London and the suburbs, yet plenty of large bushes survived in the Medway Valley, Kent, on alluvial soil overlying chalk. Mr. J. M'Gran lives in a part of the country with a mild climate suited to the requirements of shrubby Veronicas, which revel on the sea-board. *J. F.*

HARDY FLOWER BORDER.

RANUNCULUS.

Most of these hardy border plants have showy double flowers. December is a suitable month in which to plant the roots, which may be classed as tubers. A good method of growing Ranunculuses is to procure a shallow box, fill it with sharp sand and lay the roots singly, claws downwards, on the top. Stand the box on a shelf in a light, frost-proof shed, and keep the soil just damp until February. The plants will then be well rooted in the sand, and should be planted in the border, carefully, six inches apart and two inches deep.

Ranunculuses will succeed in any good garden soil, but the best rooting-medium is one containing plenty of leaf mould and well-decayed cow manure. These materials should be incorporated with the soil not later than the middle of December, and the tubers may be planted at the same time if desired; if planted in winter they should be placed a trifle deeper in the ground, and if embedded in coarse sand better results will be obtained.

When the foliage dies down in summer the roots should be lifted, dried and stored until the following December.

The Turban kinds are the best to grow, these having large, double, rose-like, self-coloured flowers, and being much more hardy than any of the other varieties. The chief colours found in these handsome varieties are yellow, white, scarlet, rose, orange and crimson.

This type grows just over a foot high and makes a useful addition to any border, producing a fine display of flowers in early summer; the plants will grow to perfection in soil with a cool base and in slight shade. *W. Miller, Wurley, Essex.*

The Week's Work.

THE ORCHID HOUSES.

By J. T. BARKER, late Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

Mexican Laelias.—These Laelias, of which L. anceps is the principal, include a whole series of beautiful varieties, with flowers ranging from pure white to the richest colours. The early, or coloured varieties, are in bloom, and these will be followed by the exquisite white forms. At the present time these plants are not cultivated so extensively by Orchid lovers as their merits deserve. Being easy to cultivate, and flowering during December and January when Cattleya blooms are scarce, a series of them should be grown where choice flowers are in demand the whole year round. By judiciously manipulating the plants their blooming period may be considerably extended where they are grown in sufficient quantities. Should it be desirable to hasten the flowering of the late varieties, they will readily respond to increased warmth, likewise they are easily retarded by keeping them in a temperature of 55° with very little water at the roots. No harm will accrue to the plants at this season by growing them in a moderately dry atmosphere. When these Orchids have finished flowering, water should be almost withheld, but the pseudo-bulbs must not be allowed to shrivel.

Potting.—If during the winter any of these plants begin to send out roots from the last formed pseudo-bulbs, they should be repotted, but it is not advisable to disturb them more than is absolutely necessary. Half pots or deep pans are the best receptacles, and, owing to the large amount of water these plants require whilst growing, exceptionally good drainage should be afforded them. They should be potted firmly, and the best compost is coarse Osmunda fibre. These Orchids need an abundance of light at all seasons, and fresh air in quantity in accordance with the weather. Whilst opening their flowers a temperature of about 60° with a proportionate rise with sun heat is suitable.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to J. A. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Melons—If ripe Melons are required by the end of April seed should be sown now. The house or pit devoted to growing early Melons should be well heated, and so constructed that the plants will receive the full benefit of the few hours of sunshine that occur during the early part of the year. The plants should receive no check whatever, and to ensure this there should be sufficient top and bottom warmth to maintain the requisite temperature without heating the pipes to excess. Most growers have their own fancy as regards the variety to grow for early cropping, but to those in doubt I would recommend Hero of Lockinge as one of the best and earliest sorts. The fruits of this variety are not large, but the plant is sturdy, sets fruits freely, and the latter are of excellent flavour. At Woolverstone we sow two seeds in a medium 60-sized pot. The soil for the early sowings should be moderately light in texture and should not be pressed down on the seed after filling the pot, a sharp tap on the potting bench being all that is needed. Germinate the seeds in a brisk heat with atmospheric moisture; provided the soil is moist when the seeds are sown, watering will not be necessary until the plants are above the soil, when they should be removed to a position near the roof-glass to promote sturdy growth. We usually leave the two plants in each pot until after planting, when the weaker one of the two is removed. The plants should be secured to small stakes to keep them erect. The fermenting material of which the hot-bed is to be formed should be prepared and placed in the house a few days previous to planting. The soil may be either placed in mounds, or as a continuous ridge, and it should be on the hot-bed in time to allow it to become warmed through before planting takes place. To encourage a free root action it is advisable to use a lighter mixture than for later plants, which grow under more favourable conditions. The temperature should not fall below 60° at night; 5° to 10° higher by day, and a further rise by sunheat will be very beneficial to growth. Very little ventilation will be required until the flowering period.

THE FLOWER GARDEN.

By C. TURNER, Gardener to EMILY, LADY AMPTHILL, Ampthill Park, Ampthill, Bedfordshire.

Deciduous Hedges.—Most gardens contain one or more deciduous hedges, as they are useful for screening unsightly objects, breaking the wind, or as dividing lines between different parts of the garden. Where they exist, such hedges should be trimmed more or less according to their growth and the position they occupy. A Beech hedge should not be cut so closely as, say, a Hawthorn hedge—the former being less responsive to the pruning tends to produce a host of twigless, hard snags or short stubbs, and thus loses much of its beauty and use. Where a Thorn hedge has grown too tall, it is by far the best plan to pleach it (or lay it, as it is more often termed in the west counties), after which operation the hedge will become bushy with growth from the base again.

Rose Briar Hedges.—Hedges of Briar Roses may also be pleached at this time, if desired; or a quicker way of dealing with such hedges, where labour is scarce, is to cut the growths down with the pruning shears to varying heights, so as to avoid a stiff appearance both now and when growth is active. Lime trees covering alleys or entwined as hedge-shields should also be pruned back, and any necessary extension of training attended to.

PLANTS UNDER GLASS.

By JOHN COUTTS Assistant Curator, Royal Botanic Gardens, Kew.

Alpinia vittata.—This beautiful variegated species when grown in a large pan makes a fine specimen for the stove. Unlike some other species of Alpinias which may be partly rested during the winter, this plant should not be dried off, although the roots should be watered with extreme care during winter. Alpinia vittata is best increased by division during the spring, when it is commencing to make fresh growth.

Cannas.—Where Cannas are grown in small pots for furnishing the plant stages, a portion of the stock may now be started into growth. The rhizomes should be shaken out, and strong portions selected for potting, trimming off all old or decayed portions. The prepared rhizomes may be laid out in a bed of fibre until they start into growth, or they may be placed direct into 48-sized pots, from which, in due course, they should be shifted into six or seven inch pots, in which they will flower. Cannas need a rich compost and plenty of feeding when in full growth. At this stage they should be grown in a house having a temperature of 55° to 60°. Under this method of cultivation the growth is best restricted to one strong shoot; with plenty of stock available a display may be maintained from May until late autumn. Very little water should be given the plants in their earlier stages of growth as the rhizomes are very apt to damp off. When growing freely they need ample supplies of water at the roots. Canna rhizomes are much weakened by being kept too dry during the winter they keep much better and start into growth more readily if they are stored on a moist, earthen floor.

HARDY FRUIT GARDEN.

By A. J. HARTLESS, Gardener to Major J. F. HARRISON, King's Walden Bury, Hitchin, Hertfordshire.

Bush Fruits.—Black and Red Currants fruit on young and old wood respectively, therefore the method of pruning them differs. Red and White Currants produce their fruit on spurs developed on shoots of two or more year's growth. It therefore follows that two or three year old wood should be encouraged, older shoots producing only small racemes of fruit. A bush of these fruits should only consist of six to eight main stems, and fresh ones may be allowed to develop to replace one or two of the older ones each year. The Black Currant produces its fruit on the shoots of the previous year, therefore plenty of one-year-old shoots are necessary to obtain satisfactory crops. It is always advisable to have a reserve stock of young Currant and Gooseberry bushes to take the places of those of doubtful age. Gooseberries make free growth and need severe pruning. In some districts the destruction of the buds by birds has to be guarded against, and in such cases the pruning is best deferred until the spring. It is equally important too, with Gooseberries, to encourage the development of three-year-old wood. Raspberry plantations should be kept free of weeds, and if the ground in the rows is tilled, the work should be done by carefully forking it to prevent damaging the roots. Proceed with the pruning and training of wall bush fruits as weather permits.

Pruning.—Proceed with this work as opportunity will allow. In the case of large limbs, care must be taken to cut them back to the main stems, leaving no spur. If necessary, employ a broad chisel when the saw cannot be used, in order that the wound, however large, may callus over. Nothing is more detrimental to any tree, whether fruiting or ornamental, than to leave snags which may admit disease and insect pests and prevent the bark from covering and healing the wound quickly. It is far better to make a larger wound to get the cut right back to the main stem than cut to a smaller diameter a short distance away, and such cut surfaces will heal much more quickly. All wounds made in this way should be coated with gas tar.

THE KITCHEN GARDEN.

By R. W. THATCHER, Gardener to MARK FIRTH, Esq., Carlton Park, Market Harborough, Leicestershire.

Mushrooms.—Beds that have become exhausted should be removed from the house, and the spent manure stored in a dry shed for mixing with soil for a variety of purposes. A supply of fresh horse-droppings should be secured, and turned several times preparatory to making fresh beds in the same house. The ammonia from the manure will greatly benefit the existing beds, and the extra warmth from the material as it ferments will help the other beds to continue producing Mushrooms in quantity. Soil from an old pasture is the best material for covering the manure when the beds are spawned, and it should be cut and carted when the weather is open and dry. The soil should be passed through a coarse sieve, retaining as much of the fibre as possible. Beds in the open should be well protected in severe weather by covering them with plenty of long stable litter.

Horse Radish.—Roots of Horse Radish may be lifted and stored in sand if the ground is required for other purposes. Pieces of the roots, each with a crown, should be tied in bundles and stored separately, so that they may be ready at hand for planting whenever the ground is in a suitable condition. The ground should be dug deeply. The finest and best flavoured roots are produced by planting annually.

LATE AUTUMN IN THE ROCK GARDEN.

IF, as autumn advances, the cultivator of Alpine plants gets worried because the rock garden is not so gay and interesting as it was during spring and summer, he may be sure that either his ideals are wrong, or the rock garden is at fault. Possibly a little of both. Folk are apt to long for a state of perpetual spring in the garden, an ideal which, if it could be realised, would be unutterably boring. Autumn may be, in fact should be, a comparatively flowerless time in the rock garden, and yet if things are ordered properly it should be a good time, full of interest and beauty.

Autumn and winter are certainly the seasons which impose the severest test upon good planning, right placing of rocks, and tactful use of dwarf trees, shrubs, and tiny Conifers. In summer a succession of easy triumphs of sheer blossom will cover a multitude of geological sins. Rocks tend to become mere frames and settings for the plants, and dwarf Pines and Junipers become foils—a relief to the eye amid a flux of colour. When flower time is over the rocks themselves assume a greater importance. Both they and their Mosses and Lichens seem to grow sleek under autumn rains, and much more beautiful. The small trees, too, stand out with greater importance as features of the landscape. How easy it is to sneer at unskilfully placed rocks with the time-worn jest about "a pudding stuck with almonds," and how difficult it is to use rocks well, and lay them so as to satisfy even one's self! And how difficult, too, to place dwarf trees in such a way that they do not look as incongruous as sprigs of Parsley garnishing a pudding!

I think, however, that the two most important things that experience has taught me in this view of rock gardening are, firstly, to set out to arrange rocks and trees in such a way as to please myself—and let all critics talk themselves hoarse; secondly, not to worry too much about immediate effect. Rain, wind and weather will work wonders with a dwarf tree after it is planted. It may strike an awkward attitude when first put in, but in a year or two it will grow to its position, and the branchlets and leaves will naturally assume the poise most appropriate to the tilt which you have enforced on the trunk.

A fault which is too common in rock gardens in autumn and winter is that there are too many large spaces of bare soil. In nine cases out of ten these dreadful, bald spots might be clothed with judicious plantings of the common downland Thymes, Thymus Serpyllum, and its varieties, without injuring the deciduous plants underneath. Many of the Campanulas, especially C. carpatica, go offensively bald in winter. Over a carpet or scattered, rather than massed, should be the method of planting them. The Serpyllum Thymes are glorious plants in all their forms. There are the white-flowered form, the crimson coccineus, the even showier coccineus major, and the common Heather-purple wild type which mixes inimitably with dwarf Campanulas on the slopes, or with yellow Stonecrop on the path. I have recently acquired a pale, flesh-pink form which promises well, and a tiny dwarf called minor, which should make an ideal carpet to keep Gentiana verna happy. But for winter effect the best of all Thymes are the woolly-leaved T. Serpyllum lanuginosus and the golden T. Serpyllum aureus. Put the woolly Thyme where it may trail out and down over a rock, and soon it will form a rounded mass of most attractive quaker-grey felt. The golden Thyme is somewhat of a new comer, and is golden only in winter. All the summer it is just ordinary Serpyllum, green leaved, and "purple" flowered. In autumn the whole plant turns as gold as a guinea, and so remains through the dead months a most cheerful note which may even be enjoyed by folk who look upon variegated foliage as unpleasantly diseased leaves, for this gold of the Thyme is in the nature of an "autumn tint" rather than variegation. Golden foliage may very easily be overdone in the rock garden, but a splash of colour here and there gives a pleasant, warming, sunny effect. One of the best plants I know for suggesting mid-winter sunshine is the golden form of the common Ling, Calluna vulgaris aurea. The whole plant, both in winter and summer has the most delicious effect of rich autumn colouring—gold, shading into curious coppery reds and crimsons—and like all Heathers this plant is at all times picturesque in form and growth.

It is neither right nor natural that there should be many flowers in the rock garden in late autumn and winter, and it is a mistake to mourn their absence or to overdo such flowers as will come naturally there. Polygonum vaccinifolium will remain in flower until cut by frost, and is one of the loveliest of late autumn rock plants. Give it a warm, sunny slope, and, if possible, a raised and rounded rock over which to drape itself, or a sharp little precipice over which to cascade. It is a rapid trailer, and makes a perfect forest of 2-inch to 3-inch spikes of warm rosy pink.

Where it is really happy, as here at Stevenage, Gentiana acaulis will nearly always give an odd trumpet or two at intervals throughout the winter. By acaulis I mean the old garden form about whose origin and real name the horticultural savants hold such argument. But none of them *know* whence it came or what rightly to call it, any more than they know what it wants in the way of soil. Who can say that he has ever seen this particular form, this exact species or variety of Gentian, wild in the Alps? All we know is, that it has been in cultivation for a very long time; that if it likes your soil it will flower; if it does not it will not; and that it is easily among the "best" alpines.

Lastly, let me introduce my very good friend Gentiana sino-ornata. This Gentian is a perfectly glorious and splendid plant, which, until recently, has greatly bothered me in the growing. But I think I can now give a fairly certain recipe for success. I think it dislikes lime, and I am quite sure it dislikes hot, stiff soils. What it does like is a soft, rich mixture of peat, leaf mould and silver sand. Give it a bed of these materials and it will form lush turves of glossy green foliage, and then in autumn—September, October, and November—it will cover itself with a wild profusion of great sapphire trumpets, trailing-stemmed and upturned. The brilliant, wide-mouthed trumpets are as large as those of G. acaulis, and as an added splendour they are striped, in panels, outside, with lines of dull blue and sapphire on a ground of dim, old ivory. *Clarence Elliott.*

HYBRID APPLES.

PYRUS DIVERSIFOLIA × CULTIVATED APPLE.

PYRUS DIVERSIFOLIA (the P. rivularis of Douglas) is one of the few deciduous trees of the West Coast of Vancouver Island, where in the dense, evergreen, Coniferous forests it attains a height of 20 feet to 30 feet. This Pacific Coast Crab Apple seems more primitive and obscure than either P. Malus or P. baccata, and in hardness of wood and habit of growth resembles Crataegus brevispina. Its corymbs of small white flowers open a little later in spring than those of the majority of Apples; the dull yellow, oblong, obovate, rarely round fruits seldom exceed half-an-inch in length, and after a very little frost they turn to watery pulp, little resembling an Apple.

In 1913 the writer fertilized a few flowers on a branch of a tree growing by the edge of the forest with mixed pollen of the following nine varieties of Apples:—Lemon Pippin, Ribston Pippin, Grimes' Golden Pippin, Gravenstein, Lord Suffield, Belle de Boskoop, Ontario, Northern Dumpling, and Beauty of Moray; from these crosses fifteen seedlings were raised, ten of which, for some unknown reason, refused to grow more than a foot or so high. The remaining five are normal in growth, and the illustration (Fig. 134) shows three of the hybrid fruits, with examples of P. diversifolia in the foreground.

FIG. 134. PYRUS DIVERSIFOLIA × CULTIVATED APPLE.
THE THREE LARGER FRUITS ARE HYBRIDS AND THE SMALLER ONES IN THE FOREGROUND THOSE OF P. DIVERSIFOLIA.

The hybrid Apple on the left is a decidedly late variety, with the skin beautifully sprinkled with bright red on the sunny side. The middle Apple has the pearly-white, stomata-like spots showing through its pale yellow skin, as in some of the old Golden Pippins. The specimen on the right is an early variety and inclined to decay on the tree. All three, when cooked with a little sugar, are pleasantly acid to the taste and a decided improvement on the astringent fruits of the Siberian Crab Apple and its varieties. It will be noticed that the calyx is persistent in the hybrids; in the seed parent it is nearly deciduous.

P. diversifolia is hardly, if at all, subject to the form of canker prevalent on the Pacific Coast—so deadly to the cultivated Apple wherever the rainfall is heavy—and the object in view in this cross was to see if the immunity to canker in P. diversifolia could be transferred to cultivated Apples. A long time must elapse ere this can be ascertained. In the meantime one of the hybrids has been crossed again, on this occasion with Devonshire Quarrenden, and the second generation seedlings look as though they had more variety in their wood and foliage. *G. Fraser, Ucluelet, B.C., Canada.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

MR. KINGDON WARD'S SEVENTH EXPEDITION IN ASIA.*

No. 26.—BACK TO CIVILIZATION.

IN the hills there is more variety of vegetation. Some of the narrow valleys are filled entirely with Bamboo; elsewhere Palms and Screw pines predominate. The former include Fan Palms (Borassus), used for thatching; climbing Palm, or rattan, used for the support cables of suspension bridges; Sago Palm, cultivated in most villages; and an almost stemless species with large, pinnate leaves provided with trident thorns down the midrib.

Elsewhere are groves and belts of wild Banana, which is particularly abundant in the flat, wide valleys of the larger streams. Two varieties are found in the hills, one kind having the under surface of the leaves and petioles (hence also the "stem") covered with a very fine, floury white meal, the other without this embellishment. The Kachins distinguish them, calling the former *lagyep*, the latter *ngakrop*. The inflorescence of the *ngakrop* is boiled and eaten, but neither yields an edible fruit. The two grow side by side, and I could distinguish them in no other way than that described.

A clump of *lagyep* flapping its leaves in the sunshine was a pretty sight, the silver white coming to the surface here and there like foam on a bright green sea.

In the valleys, according to Kachin lore, grow two other species, also found cheek by jowl, though they do not mix with the hill species. One of them is a dwarf plant with narrow leaves; the other is rather tall. I must confess I could not distinguish these two myself, though we must have seen plenty of both of them. The inflorescence of the dwarf, like that of *ngakrop*, is boiled and eaten. This, however, is not a regular article of diet, but either a delicacy or more probably resorted to in times of famine.

In shady places, the big leaf-blades of these plants, when young, stand vertically with all sail spread, so to speak; but on sunny slopes, and as they grow old and jaded, the two halves of the leaf droop down on either side of the midrib like the pages of a book, giving a very dejected appearance to the plant. The final stage is reached when the leaf, cut into strips by the wind, hangs in tatters.

At this season flowers were rare, particularly in the lowlands. In open thickets a few twining Convolvulaceæ lingered on; and in the jungle the short fat pokers of a Phlogacanthus, the gaping, purplish-pink flowers craning their long necks, were abundant. By the way-side were small weed-like Acanthaceæ, one species having lurid magenta flowers.

On heavily-shaded banks, never reached by the sun's rays (at least not at this season), and consequently always moist, grew clumps of pale yellow flowered Chirita; and this remained with us for many day's march.

About the ninth day south we saw the snow-clad Lohit divide, now a hundred miles distant, for the last time. It was very faint—a white line across the enamelled blue of the sky.

The road follows a different alignment to what it did eight years ago, when I first visited Hkamti. After traversing the plain, it crosses and recrosses the Mali Kha itself within a few miles—this to avoid the dangerous passage of a tributary on the right bank, which it was found impossible to bridge.

Keeping to the lowlands for several marches, it then winds up through the hills as before, but never achieves such altitudes as formerly. Nor are the gradients so steep. Probably no point on the modern road much exceeds 3,000 feet altitude; whereas the old road frequently climbed to 5,000 feet. In fact, the new road is just about as good a road as can be made through these jungly hills. After passing the half-way mark, flowers became more numerous. On January 4 I dived into the jungle and emerged triumphant with a canary-yellow ground Orchid, and a Strobilanthes new to me. This latter had an uncommonly large, pale violet flower. The plant, though too weak to stand erect, grows many feet in height, finding support in the surrounding vegetation.

It is difficult to penetrate the hill jungle, on account of the dense undergrowth. There are plants which prick and stab one, and tear one's clothes; others which trip one up, or forcibly oppose progress. But occasionally one strikes a track, and then, after a little time, surprising things come to light.

There were plenty of Orchids on the trees, though not in flower, except one Coelogyne. Thus I was able to bring home plants of Cymbidium, Coelogyne, Eria, Dendrobium, Bulbophyllum, Saccolabium, Pholidota, Phaius, &c.—plants doubtless of no value to horticulturists, but botanically interesting.

On January 5, when we were within a hundred miles of Myitkyina, more flowers turned up, including a white-flowered Clerodendron, also Thunbergia sp. (a solitary, blue-violet flower), and an Acanthous herb, which had prickly, Thistle-like leaves. It was curious how the Acanthaceæ had almost a monopoly of the flowering plants.

No tree was in bloom, though a few showed symptoms. Neither were any trees bare of leaves—most of them drop their foliage in the hot weather, and the new leaves develop almost immediately. On this same day a change began to steal over the jungle. New species appeared, of which the Tamarind tree and a Cassia were the most noticeable. We were getting down into the strictly monsoon forest.

On January 6, 1923, I observed more additions to the vegetation—two new Palms. One had tall, smooth, reed-like stems, crowned by a plume of small, pinnate leaves (Areca). Another had a stumpy stem hidden by the bases of old leaves, with their basket-work sheaves, and immense pinnate leaves, silvery beneath and without thorns.

A small, root-climbing Ficus, with leaves flattened against the bank, and very neatly set, was abundant. Also mysterious-looking Gesnerads of the Didissandra, or Ramondia type, Ferns, Lycopodium, Selaginella, and other unfamiliar plants, with quaint or picturesque foliage. On sunny banks Polygonum capitatum was common. Another excursion into the heart of the jungle brought to light a curious undershrub in fruit. It had scarlet pods, hanging in fours. Another had pairs of follicles, green without, orange inside, with crimson seeds. There were also patches of Strobilanthes with purple flowers and close to Myitkyina a third species, with white flowers, appeared.

FIG. 135.—THE MALI KHA, THIRTY MILES FROM THE CONFLUENCE.

Even here the contrast between the vegetation on the north and south slopes is marked. On the former, and in deep ravines where the mist lurks late, is big tree jungle—the real Indo-Malayan type. On drier slopes and in open valleys facing south are dense tangles of Bamboo, shrubs, and small trees.

On January 8, we reached the Mali Kha (Figs 135, 136) once more. Here were masses of Begonia, and on sand-banks in the river bed actually a Violet; it was like a message from home!

We were now only forty miles from Myitkyina, rail-head and civilization. Already the plains, or rather the mouth of the Mali Valley, where eastern and western branches unite to form the Irrawaddy of commerce, were visible. Henceforward the road was practically level.

A wee violet-flowered Torenia; two Acanthous weeds (one with two kinds of leaves); a second species of Phlogacanthus bearing spikes of ruby flowers, but smaller all over than the previous species (which also occurred here); and bushes of chalk-white, fragrant Jasmine, were the pick of the flowers. Yet, had I collected everything I saw — every

* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, 29, 1921; January 7, 21, March 11, 25, April 8, 22, May 6, 20, June 3, 17, July 1, 15, 22, August 5, 26, September 9, 23, October 7, 21, November 4, 18, December 2, 16, 30, 1922; January 13, 27, February 10, 24, March 10, 24, April 7, 21, May 5, June 2, 23, July 7, 21, August 18, September 1, 29, October 20, November 2, 17, and December 1, 1923.

Digitized by Google

unworthy little Composite and miserable Polygonum, I doubt if I should have amassed fifty species down the Putao road. Even here winter had come.

On January 11 I did my last march. The remaining twenty miles was to be done by steam launch. We went on board at eleven o'clock, and two hours later stepped ashore at Myitkyina. The journey was over.

Ever since leaving Hkamti Long I had been looking forward to the end of the trip; but once in civilization, I began to look back on it with regret. Even the anti-climax had been pleasant. However, that is always the way, and caused no surprise. *F. Kingdon Ward.*

THE END.

NOTES FROM WISLEY.

CHANGES in the colour of the foliage of shrubs and trees during successive seasons, and the reasons for them, would make an extremely interesting subject for study. The autumn is usually associated with the most beautiful effects, but in certain plants winter is the season of climax.

A common instance is that of Berberis Aquifolium, the leaves of which turn to rich reds and purples during winter, and when dusted over with hoar frost are most attractive. In winter also, certain Conifers which normally possess a bronzed appearance develop a much more intense colour. This is seen in certain varieties of Cupressus, and particularly in the case of Cryptomeria japonica elegans, of which there is a large specimen in the rock garden at Wisley. Although damaged in previous years by heavy falls of snow, it is still ornamental in habit, and the present dark chocolate-red colour of its leaves makes a good background for the silvery foliage of Atriplex Halimus growing at its base.

Another Conifer in the rock garden exhibiting this winter colouring is a plant of Thuja orientalis Spathii, which has formed a roughly spherical bush, barely fifteen inches high, although it has been growing here for a considerable number of years.

In the Alpine house also there are examples of coloured foliage. Azalea amoena has bright-red leaves, and Calamintha barosma has purplish, Thyme-like foliage. This recently-introduced plant is remarkable for the very pungent odour emitted when the leaves are bruised, which resembles and rivals that of Menthella Requienii. The flowers are pink and large in comparison with the leaves. In this house a few Primulas are to be seen in flower, including P. viscosa, P. Juliana, and P. megaseaefolia. The last, however, has no business to be flowering now. Another freakish occurrence has been discovered in one of the propagating pits, where some plants of Primula capitata have been making proliferous growth. In one case so many as five shoots were sent out from the flower head, each bearing a subsidiary inflorescence.

Three plants each of some three-hundred-and fifty stocks of perennial Delphiniums have been planted for trial, and the merits of many kinds of Dianthus, including D. Allwoodii, Pinks and border Carnations are also to be determined, while, under glass, trials of annual Delphiniums and Schizanthus are in progress.

In the trial grounds Gentiana acaulis has for a long time been grown as an edging and has always done very well there the ground being much less dry and sandy than in other parts of the gardens. Although the normal flowering season is late spring, numbers of blooms are to be seen at the present time; in fact there are few occasions throughout the year on which it is impossible to find one or more of the brilliant blue flowers of this plant.

In this field garden large numbers of Heaths in great variety are being planted in stretches which will occupy about an acre of ground when completed. Among these are to be seen a few groups of suitable trees and shrubs, such as Pines, Birches and Brooms. *J. G. White.*

YOUNG LADS AND HORTICULTURE.

QUITE recently a communication reached me from the secretary of an organisation which concerns itself with the welfare of lads. He stated that many boys who have passed all their examinations in elementary schools are still at school for the simple reason that they cannot obtain employment, and he asked if I could do anything to secure openings where the boys would have an opportunity to learn gardening.

It is strange that this should be so at a time when, from careful observation over a wide-spread area, one realises with some concern that there are very few lads and youths in gardens and nurseries to-day who show signs of making good gardeners and plantsmen to carry on the craft after the veterans of to-day have laid down their tools. It is no mere idle fancy of narrow-minded old age which simply will not admit that the present and rising generation can be as clever, industrious, and enthusiastic as the last; but it is the plain and simple fact that we have not in professional or commercial gardening circles to-day a sufficient number of lads in training to fill the ranks as they must inevitably become depleted. With that fact admitted, and coupled with the authoritative information that boys are crowding elementary schools, thus hindering the progress of their juniors, simply because employment cannot be found them, we must surely admit there is a problem to be solved.

Every good gardener and every nurseryman who is a true horticulturist must feel that it is a part of his life's work to train a youngster to his calling, for the future of horticulture is to that extent in the keeping of the horticulturists of to-day. Furthermore, every good citizen must be considerably concerned about the welfare of the lads who should be engaged in some useful occupation, and fitting themselves for the sphere of manhood, for wasted youth may too easily be the prelude to wasted manhood.

Unfortunately, the simple recognition of the existing needs and even the personal desire to do the right thing cannot completely solve the problem, for there are very stubborn obstacles in the way. When I was a boy, it was customary for well nigh every head-gardener and every nursery foreman or propagator to have a lad constantly beside him, not merely to do odd jobs but, if he showed aptitude and interest, to watch and learn how the work of a gardener or a plantsman should be done; at that time, a young lad's wages were, maybe, half-a-crown or three shillings per week, and not more than five shillings a week for the second year. Even though the half of the boy's time might be occupied in watching and learning, the expense was small, and if the lad was keen it was a delight to the gardener to teach him, while the effort was repaid when the lad had learned sufficient to be useful. In this way beginners learned the practice of horticulture by a mastery of detail and knew their work thoroughly from beginning to end.

To-day, however, a lad must earn what were then the wages of many men. The consequence is that of necessity fewer lads can be employed, and whoever may be responsible for a lad's employment is bound to see that he does sufficient work to earn his money. This means that lads are put at ordinary labouring work that requires no skill, and they must work fairly well to earn their pay. There is no time for teaching because time costs too much money.

The majority of parents are obliged to demand the highest possible wages for their sons, and it is by no means a rule that the lads whose parents can afford to waive the question of wages are the best or the most promising of pupils.

We cannot ignore facts, and if we are reasonable we must admit that, not alone can either parents nor employers over-ride the obstacles.

When I was a youth, I remember a wealthy gentleman who had been a great patron of horticulture, provided a sum sufficient to enable two lads to receive three years' training in a good nursery, and then start them off in their first situation with a trunk of clothes and some cash. Two fresh lads took the places of those that had gone, and then another two. Four out of those six lads I have met on various occasions in recent years, and they have carved out for themselves highly successful careers. There never was so great a need for similar philanthropy as to-day. It is not scholarships to horticultural colleges that are so urgently needed, but facilities for the placing of lads who have a bent for horticulture in good gardens and nurseries. The Royal Horticultural Society is wealthy. What a grand thing it would be for it to assist in such a scheme, not solely by providing tuition in its gardens at Wisley, but by assisting in the maintenance of lads in training in gardens and nurseries. This, surely, is a work of both horticultural and national importance. *A. J. Macself.*

GARDENERS' MUTUAL IMPROVEMENT SOCIETIES.

A RECENT experience has prompted these notes, in the hope that they may be helpful in aiding the formation or furthering the development of Gardeners' Mutual Improvement Societies. As a rule it is not easy to create sufficient enthusiasm to maintain the interest in such societies and to keep them flourishing, notwithstanding the obvious fact that periodical meetings for the mutual discussion of difficulties and exchange of views are of educational value.

It is, therefore, extremely pleasant to find a society where the management has succeeded in arousing so great an enthusiasm that full meetings and animated discussions may be relied on. The Reading Gardeners' Mutual Improvement Society is such an one.

It was gratifying to learn that this old Society is still increasing its membership, indeed, at every meeting held during the current year new members have been introduced. The meetings are held fortnightly throughout the year, and are always well attended, and one of the difficulties with which the secretary will have to contend in the near future is the provision of sufficient accommodation. At each meeting arrangements are made for the reading of a paper on a horticultural subject. Exhibits of vegetables, flowers, and fruits are also staged, and some of those I saw were well worthy of the Chelsea exhibition. Prizes and certificates of merit are awarded to successful competitors. In the summer visits are arranged to gardens and places of interest in the locality. A special annual outing is arranged to visit some more distant place of interest.

Gardeners are not uncommunicative, but are always ready to pass on information for the benefit of others. I found this spirit, however, particularly in evidence among members of the Reading Society. As an example I may quote the instance of a member who staged Fig-trees, in pots, only eighteen months old from the cutting, yet laden with ripe fruit, and who gave the fullest details concerning the propagation and culture of his plants. This unselfishness in co-operating for the mutual good may be one of the chief reasons for the flourishing condition of this Society.

Reading is, of course, a specially favoured locality to those interested in horticulture. The value of the scientific and practical contributions made to horticulture by the staff of Reading University Gardens is well known. The members of the staff attend the meetings and make valuable contributions to the discussions. The fame of Reading seeds is also world-wide. In such an atmosphere it is not surprising that interest in horticulture is stimulated to an unusual degree. Notwithstanding these advantages it will be obvious that such striking success could not be attained without organizing ability and a committee working in harmonious co-operation, to which must be added the genial personality of the secretary.

The meeting I attended at Reading reminded me of two or three decades ago when, if memory does not deceive, enthusiasm was more widespread in spite of fewer facilities. In those days, almost every small town or village had its horticultural society, which held frequent and well-attended meetings, and it was not unusual for young gardening enthusiasts to walk many miles through muddy country lanes on dark nights to be present. As for the annual show, this was, without exception, the village event of the season. Probably the war was the cause of the dissolution or decline of many of these societies, some of which have not been revived or have not yet fully recovered from the effects of suspended animation. There is, however, no good reason why Gardeners' Mutual Improvement Societies should not only recover lost ground but show increasing membership and interest.

Gardening in some form appeals to a wide and ever-extending section of the public; there is no industry, in fact, which has such a wide field from which to attract possible new members. If a suitable programme is provided, calculated to stimulate and maintain interest, there will be no lack of membership for such societies. The following suggestions are made in the hope that the adoption of some of them may prove a means to this end. If the presidency of a local celebrity can be secured so much the better, particularly if he takes a personal and practical interest in the proceedings and attends the meetings. Incidentally, he will be constantly brought into touch with some of the difficulties in the way of pests, diseases, and weather conditions with which the gardener is confronted before he can gather and deliver the fruits of his labours.

Provided formalities can be dispensed with, meetings of this kind tend to foster a better relationship between employer and employée and to increase that spirit of mutual co-operation which is so essential to the success of industrial undertakings. And, after all, the modern garden is but an industrial undertaking on a modified scale. He is a poor head gardener who, as managing director of such a concern, does not endeavour to give his employer the maximum production for the minimum expenditure in labour and material, just as he is a poor employer who fails to recognise efficiency in his employées.

Prizes should be offered for the best papers on any horticultural subject read by members during the session. It is surprising how this will stimulate the zeal and interest of the members, not so much for the value of the prize as for the honour of winning it. Not only will a vast amount of information be obtained and communicated in this way to the members of the society, but the preparation of a paper is an education in itself for the author, as its delivery will have the effect of making him an expert in that particular subject.

When I was a young gardener at Kew, this system of prize-giving was a feature of the Mutual Improvement Society; prizes were also given for the best debates, with the result that a spirit of keenness to join in the discussions was created which considerably enhanced the value of the meetings.

As a variation, practical suggestions or questions might be invited from members in turn and prizes given at the end of the season for those of most value. This gives an opportunity for the practical man to shine, for there are still many good cultivators who have no literary or scientific ability.

These suggestions are intended to operate in addition to the main scheme, the essence of which is a series of lectures by horticultural experts on subjects calculated to be of practical, theoretical, or scientific value. The horticultural section of the County Council concerned is always ready to supply suitable lecturers. The Ministry of Agriculture and several of the Agri-horticultural Institutes are also able to send out lecturers who have specialised in various subjects, and are able to communicate knowledge which the ordinary gardener has no opportunity of obtaining first-hand.

In planning a syllabus the charm of variety should be remembered; no side of the subject should be wholly excluded. Often a series of lectures of the same type is arranged: for example: "Roses and How to Grow Them," "Herbaceous Borders and their Upkeep," etc. While the practical value of such lectures is obvious, it is desirable to include a proportion dealing with general principles such as those pertaining to chemistry, botany, biology, and vegetable physiology. It must not be forgotten that in horticultural education, as in all forms of education, it is more important to master principles than details.

Care should also be taken not to cultivate too intensively that national trait of character—insularity. However good and capable the members of a society may be, nothing but good can result from the importation of outside talent. This may often be arranged by the interchange of members as lecturers between various societies.

That great gardener, Sir Joseph Paxton, knew the value of such communal gatherings; many of the old Paxton Societies were founded under the guidance of his ideas and some of these still exist. *W. Auton*

NEW HYBRID ORCHIDS.

HOME CORRESPONDENCE.

Aster ericoides praecox.—I have been growing two forms of Aster ericoides, varying in height, habit and time of flowering, to learn in what particulars they differed from one another. In minute botanical characters they agree very closely. This year A. ericoides praecox opened its first bloom at the beginning of September when two feet high and in sandy soil; but a change in the weather checked further development till the end of that month, when the plant came into full bloom, with the flowers rather crowded on short side branches three to six inches long. These flowers all faded by the time a scattered few were open on the typical A. ericoides, which grew three and a half feet high side by side with the other. The branches on the type were twelve to eighteen inches long with more scattered and larger white flowers and green stems. The stems of A. e. praecox were purple. The value of the two forms is that they give a long succession of flowers. I had the plants from Messrs. J. House and Son, Westbury-on-Trym, Bristol. *J. F.*

Fig Trees at Lambeth Palace.—The first two trees of the Fig introduced to this country were said to have been brought from Italy in 1548 by Cardinal Pole, in the reign of Henry VIII. and planted against the walls of Lambeth Palace. These trees were much injured by the severe winter of 1813-14, but after having been cut down they had greatly recovered three years later. The Caledonian Horticultural Society visited the grounds in September, 1836, but the old trees had disappeared some years previously when the palace was undergoing repair. There were, however, some young trees raised from cuttings and growing in the Archbishop's kitchen garden. The trees now growing there were most likely planted in their present position soon after the Scottish society's visit, so that they would be about ninety years old, and parts of the original ones. The trees all lean away from the wall very much and one of them was partly broken and brought down on the grass by a gale early last September, and its recovery is somewhat doubtful, unless the large limb resting on the grass roots into the soil during the coming season or two. In warm seasons the trees ripen a considerable quantity of fruit, and this says much for the climate of London and for untrained trees. *J. F.*

Boenninghausenia albiflora.—I read with interest in your issue of December 15 (p. 351) the note by Mr. Grove on Boenninghausenai albiflora. In this note he makes a statement which I must refute. Mr. Grove states: "From this we may conclude—did not we already know—that the species, which Farrer never saw in his Asiatic travels, did not prosper in Ingleborough." I was with Farrer in Upper Burma during 1919, and we saw masses of what has definitely been named Boenninghausenia albiflora below Itpimaw Fort at an altitude of 8,000 feet. There it grew on a rather hot, sunny bank, and we never saw a plant over a foot high. I have plants growing in my garden from seed collected by myself. They are planted in a sheltered portion on the banks of a stream. Although it is extremely healthy and obviously at home, in no case does the plant exceed a foot in height. There are two possible explanations for Mr. Grove's large plants. One, that his seed is not that of the true species. I have not heard of an importation of this seed from India for many years. The second explanation, which is the more likely, is that it is a plant which varies enormously in its native habitat. I can only draw attention to Rhododendron aureum. When Forrest first found it, it was distinctly an alpine plant never growing more than eighteen inches in height. Last year he found it again as a plant of eight feet and with no more attributes of the dwarf than I have. I can also affirm that Boenninghausenia albiflora flowered in Burma, and also with me in Scotland, during July and August. *Euan Cox.*

SOCIETIES.

ROYAL HORTICULTURAL.

TRIAL OF EARLY-FLOWERING CHRYSANTHEMUMS AT WISLEY.

THE following awards have been made by the Royal Horticultural Society to early-flowering Chrysanthemums after trial at Wisley:—

AWARDS OF MERIT.

DECORATIVE VARIETIES: White: *Candida*, sent by Messrs. LOWE AND SHAWYER; *Sanctity*, sent by Messrs. DOBBIE AND CO., Mr. H. J. JONES, Mr. W. H. SIMPSON, Messrs. BARR AND SONS, and Mr. I. GODBER; *Excelsior* (*syn. Sanctity*), sent by Messrs. R. H. BATH, Ltd.; *Framfield Early White*, sent by Messrs. DOBBIE AND CO., and Mr. H. J. JONES; *Framfield White*, sent by Messrs. R. H. BATH, Ltd., and Messrs. BARR AND SONS; *Roi des Blancs*, sent by Messrs. DOBBIE AND CO., Mr. H. J. JONES, Mr. I. GODBER, Messrs. R. H. BATH, Ltd., and Messrs. BARR AND SONS; *September White*, sent by Messrs. DOBBIE AND CO., Mr. H. J. JONES, Messrs. R. H. BATH, Ltd., and Mr. I. GODBER.

Blush: *Silver Lining*, sent by Messrs. H. J. JONES, R. H. BATH, Ltd., and Mr. A. W. THORPE. Nos. 55, 57, and 59 sent as Miss G. K. THORPE, by Messrs. DOBBIE AND CO., R. H. BATH, Ltd., and H. J. JONES, all are Silver Lining.

Pink: *Pearl*, sent by Messrs. H. J. JONES, Ltd.; *Normandie*, sent by Messrs. DOBBIE AND CO., H. J. JONES, and R. H. BATH, Ltd.; *Freda*, sent by Mr H. J. JONES.

Mauve-Pink: *Mme. Marie Masse*, sent by Messrs. DOBBIE AND CO., H. J. JONES, Ltd., and R. H. BATH, Ltd.; *Claret*, sent by Messrs. DOBBIE AND CO.

Purple: *Jamie*, sent by Messrs. R. H. BATH, Ltd.; *Lichfield Purple*, sent by Messrs. H. J. JONES, DOBBIE AND CO., A. W. THORPE, and W. H. SIMPSON.

Pale Yellow: *Ralph Curtis*, sent by Mr. H. J. JONES; *White Masse*, sent by Messrs. DOBBIE AND CO., and Mr. H. J. JONES; *Mrs. Bailey*, sent by Messrs. R. H. BATH, Ltd.; *Tuckswood Early*, sent by Messrs. DOBBIE AND CO.; *Charming*, sent by Mr. H. J. JONES; *Framfield Early Primrose*, sent by Messrs. R. H. BATH, Ltd.; *Southover Yellow*, sent by Messrs. H. J. JONES and Messrs. BARR AND SONS; *Willington Early Yellow*, sent by Messrs. DOBBIE AND CO.

Yellow: *Horace Martin*, sent by Messrs. H. J. JONES and R. H. BATH, Ltd.; *Elstob Yellow*, sent by Messrs. DOBBIE AND CO.; *Maggie*, sent by Messrs. DOBBIE AND CO.; *Hollicott Yellow*, sent by Messrs. LOWE AND SHAWYER; *Goldfinder*, sent by Mr. H. J. JONES; *Philip*, sent by Mr. LADDS.

Orange Yellow: *Golden Polly*, sent by Messrs. R. H. BATH, Ltd., and Messrs. PROCTOR; *Florrie Wilkinson*, sent by Mr. I. GODBER; *Miss B. Miller*, sent by Messrs. DOBBIE AND CO.; *Golden Almirante*, sent by Mr. CHATFIELD; *Vinstone Bronze*, sent by Messrs. WEBBER.

Terra-cotta: *Polly*, sent by Messrs. JONES, DOBBIE and GODBER; *Verona*, sent by Messrs. JONES, W. H. SIMPSON, BARR AND SONS, and R. H. BATH, Ltd.; *Phœnix*, sent by Messrs. SCOTT AND WICKHAM; *Well's Scarlet*, sent by Messrs. DOBBIE AND CO.

Bronze: *Hollicott Beauty*, sent by Messrs LOWE AND SHAWYER; *September Glory*, sent by Messrs. H. J. JONES AND R. H. BATH, Ltd.; *Shirley Conquest*, sent by Mr. W. H. SIMPSON; *Mrs. Jack Pearson*, sent by Mr. LADDS; *Bronze Goacher*, sent by Messrs. H. J. JONES, DOBBIE AND CO., R. H. BATH, Ltd., AND BARR AUD SONS; No. 373, sent by Messrs. BARR AND SONS, as Mrs. J. Fielding is Bronze Goacher.

Chestnut: *Crimson Polly*, sent by Messrs. H. JONES, R. H. BATH, Ltd., DOBBIE AND CO. AND W. H. SIMPSON; *Abercorn Beauty*, sent by Messrs. DOBBIE AND CO.; *Crimson Marie Masse*, sent by Messrs. H. J. JONES, R. H. BATH, AND PROCTOR; *Mrs. J. Fielding*, sent by Messrs. BATH, and DOBBIE AND CO.; *Ernest Ballet*, sent by Messrs. DOBBIE, BATH, and JONES; *Almirante*, sent by Messrs. LOWE AND SHAWYER, H. J. JONES, DOBBIE AND CO., BARR AND SONS, and R. H. BATH, Ltd.

Chestnut-crimson: *Fire-fly*, sent by Messrs. W. H SIMPSON and BARR AND SONS; *Ethel Blades*, sent by Mr. H. J. JONES; *Alcade*, sent by Messrs. LOWE AND SHAWYER; *Red Almirante*, sent by Mr. H. J. JONES.

Crimson: *Goacher's Crimson*, sent by Messrs. DOBBIE, BARR, JONES, BATH and PROCTOR; *Dick Barnes*, sent by Messrs. DOBBIE, BATH, JONES, THORPE, W. H. SIMPSON, and PROCTOR; *Jeannie*, sent by Mr. C. PRIESTNER; *Mrs. W. Sydenham*, sent by Messrs. W. H. SIMPSON and DOBBIE AND CO.

Rose-crimson: *Babia Ferrer*, sent by Messrs R. H. BATH, Ltd.

POMPON VARIETIES.

Yellow: *Flora*, sent by Messrs. DOBBIE AND CO. and BARR AND SONS.

Terra-cotta: *Orange Pet*, sent by Messrs. BARR AND SONS and R. H. BATH, Ltd.

Chestnut: *Little Bob*, sent by Messrs. BARR AND SONS and DOBBIE AND CO.

SINGLE VARIETIES.

White: *Taplow White*, sent by Messrs. BARR AND SONS.

Mauve-pink: *J. Woolman*, sent by Messrs. DOBBIE AND CO.

Orange-yellow: *Golden Firebrand*, sent by Messrs. BARR AND SONS.

Terra-Cotta: *Midnight Sun*, sent by Messrs. W. H. SIMPSON, THORPE, and BARR AND SONS; *Sunstar*, sent by Messrs. W. H. SIMPSON.

Chestnut: *Firebrand*, sent by Messrs. BARR AND SONS.

Crimson: *Ruby*, sent by Messrs. DOBBIE AND CO.; *Garnet*, sent by Mr. H. J. JONES; *Chieftain*, sent by Mr. THORPE; *Mrs. S. Smith*, sent by Messrs. PROCTOR; *Glorious*, sent by Messrs. W. H. SIMPSON.

HIGHLY COMMENDED.

The following were Highly Commended in their respective colours:—

DECORATIVE VARIETIES.

White: Blanche du Poitou, sent by Mr. I. GODBER; Miss G. K. Thorpe, sent by Mr. THORPE.

Mauve-pink: Bouquet Rose sent by Mr. H. J. JONES; Eden, sent by Messrs. BARR AND SONS, and R. H. BATH, Ltd.

Purple: No. 395 sent by Messrs. BARR AND SONS as R. Pemberton, is Rubis; No. 417, sent by Messrs. BARR AND SONS as Rubis is R. Pemberton.

Pale Yellow: Cream Perrier, sent by Messrs. DOBBIE AND CO.; Chatillon, sent by Messrs. R. H. BATH, Ltd.

Yellow: Golden Diana, sent by Messrs. BARR AND SONS, R. H. BATH, Ltd., and DOBBIE AND CO.; Mrs. R. C. Hamilton, sent by Mr. H. J. JONES, and Messrs. LOWE AND SHAWYER; Ethel Harvey, sent by Messrs. R. H. BATH, Ltd.; Leslie, sent by Messrs. DOBBIE, BATH and JONES; and Carrie, sent by Messrs. BARR AND SONS, and R. H. BATH, Ltd.

Orange Yellow: Guinea Gold, sent by Messrs. W. H. SIMPSON; Harry Thorpe, sent by Messrs. DOBBIE AND CO., R. H. BATH, Ltd., A. W. THORPE, and PROCTOR.

Terra-Cotta: Ivan, sent by Mr. H. J. JONES; Nina Blick, sent by Messrs. R H. BATH, Ltd., and H. J. JONES.

Bronze: Golden Goacher, sent by Messrs. DOBBIE AND CO., R. H. BATH, Ltd., H. J. JONES, and W. H. SIMPSON; No. 206, sent by Mr. JONES as Provence, is Bronze Provence; Provence sent by Mr. H. J. JONES No. 1 Bronze, sent by Messrs. LOWE AND SHAWYER.

Chestnut: Present Meugy, sent by Messrs. R. H. BATH, Ltd., and H. J. JONES.

Chestnut-crimson: Red Cross, sent by Messrs. R. H. BATH, LTD.; l'Argenteuillaise, sent by Messrs. BARR AND SONS and Mr. JONES; Fleube Rouge, sent by Messrs. DOBBIE AND CO.

Digitized by Google

POMPON VARIETIES.

Blush: Mr. Selly, sent by Messrs. DOBBIE AND CO.

Yellow: Gladys Gray, sent by Messrs. BARR AND SONS; Craigmillar, Mignon, and Piercy's Seedling, all sent by Messrs. DOBBIE AND CO.

SINGLE VARIETIES.

Rose Perfection, Mizpah, Rosea, and Fairy, these four varieties sent by Mr. H. J. JONES; Rosamund Hall, sent by Messrs. W. H. SIMPSON.

Purple: Merstham Glory, sent by Messrs. BARR AND SONS and DOBBIE AND CO.

Terra-cotta: Shrapnel, sent by Messrs. W. H. SIMPSON, THORPE and DOBBIE AND CO.

Yellow: Canary, sent by Mr. JONES.

READING AND DISTRICT GARDENERS'.

AT the fortnightly meeting of this association held on the 3rd inst., Mr. W. Chislett, Bill Hill Gardens, Wokingham, gave a lecture, before a large attendance of the members, on "Artificial Manures." He prefaced his remarks by asking, "Why do we manure," and answered the question by stating that it is done to sweeten the soil, to improve its texture and to set free one or more of the chemical substances locked up in the soil. The lecturer considered lime to be the cheapest and best manure for all land improvements, for with it heavy lands become more fertile and light soils are made sweeter and more productive. The following chemical manures were also dealt with and directions given for their use for various crops, viz.: nitrate of soda, sulphate of ammonia, nitrate of lime, nitrate of potash, bone meal, basic slag, sulphate of potash, muriate of potash and kainit.

In the competition for three dishes of dessert Apples there were eight entries and the judges awards were as follow:—1st, Mr. A. G. Nichols, Goddard's Farm, Mortimer; 2nd, Mr. A. W. Gower, Calcot Grange gardens; 3rd, Mr. H. Goodger, Stoneham House gardens, Calcot. In the non-competitive section a First Class Certificate was awarded to Mr. M. Goddard, Bear Wood gardens, Wokingham, for a collection of twelve dishes of Apples,; this exhibitor also received an Award of Merit for a brace of Cucumbers and a dish of Tomatos respectively. Mr. H. Wynn, Quern's House gardens, Goring Heath, staged some good specimens of New Red Intermediate Carrots, for which an Award of Merit was granted.

Obituary.

James Malcolm—We regret to learn of the death, on December 12, at Brierybush, Ewes, Langholm, of Mr. James Malcolm, who was for forty years head gardener to the Duke of Buccleuch at Langholm Lodge, Dumfriesshire. Mr. Malcolm, who was in his 83rd year, had lived in retirement for some time. He was very highly esteemed by the family he had served for so long and by all who knew him. His abilities as a gardener were widely recognised, and his death is much regretted. The funeral took place at Staplegordon Churchyard on December 14.

TRADE NOTES.

WE are informed by the Chamber of Horticulture that the International Bureau of Registration of Horticultural Novelties connected with the Federation Horticole Professionnelle Internationale, registered in October, 1923, a plant named Aralià Lizéi, submitted by the raisers, M. Lizé Freres, 115, rue des Hauts-Paves. The plant is described as a hybrid between Aralia Moseri and an Irish Ivy; fixed since 1910.

This bigeneric hybrid was described on p. 352 of our issue of December 15, under its correct title of Fatshedera Lizéi.

REMARKS.—With the exception of one or two subjects, such as Daffodils, Pointsettias, and Roses, the general supplies were sufficient for all requirements, plenty of Chrysanthemums being left over when the Market closed on Saturday morning. Prices remained normal throughout the week. The scarcest subject was Lilium lancifolium rubrum; of L. longiflorum and Richardias (Arum) there were ample supplies. All foliage advanced slightly in price, but supplies were equal for all requirements. There was not much demand for Holly; Christmas trees appeared to be selling freely, especially the smaller trees. Mistleto advanced considerably in value towards the week end. Supplies of French flowers were sufficient for the requirements, and only Anemones, red Ranunculus, and Solanum berries were limited in quantity, and these advanced considerably in price. All Narcissi and single Violets, which arrived in good quantity, remained normal in price. Parma Violets were scarce, and consignments uncertain, 10s. and 12s. per bunch being realised for them during the later part of the week.

REMARKS.—A steady trade has been done throughout the week and generally the demand has been satisfactory. Ample stocks of imported Apples, Oranges, and Grapes are on hand, not having been cleared by the Christmas demand. English Grapes have sold well, and values have kept at a satisfactory level throughout. Choice vegetables, such as forced Beans, Asparagus, and Peas have sold well at slightly higher prices. New Potatos were wanted earlier in the week, the most important consignments from Guernsey did not reach the market until Monday and were too late for the Christmas trade. Brussels Sprouts were in good demand throughout the week and finished at firm prices. The Potato trade has an improving tendency.

GARDENING APPOINTMENTS.

Mr. Andrew Taylor, previously Gardener to the late DOWAGER COUNTESS OF EGLINTON AND WINTON, at Skelmorlie Castle, Ayrshire, and JAMES COUCHIE, Esq., Castle Feddal, Braco, as Gardener to G. CRAIG SELLARS, Esq., Ardtornish, Morven, Argyllshire.

Registered as a Newspaper. With Supplement

PRICE 6d. POST FREE 7d.

SUBSCRIPTIONS—Inland or Foreign 30/- per annum, post free. *Entered at New York Post Office as second-class matter.*

Postal Address—5, Tavistock Street, Covent Garden, W.C.2. Telegraphic Address—"Gardchron, Rand, London." Telephone—Gerrard 1543.

XL ALL!—When considering the purchase of a dressing for dormant fruit trees and bushes, please remember the merits of XL ALL WINTER WASH. It thoroughly cleanses and prepares the trees and bushes for a clean, healthy start in the Spring, greatly minimising an early attack of insects. For American Blight, use it as soon as possible after the leaves have fallen. XL ALL LIQUID NICOTINE INSECTICIDE provides the finest dressing for Vines, Figs, Peach Trees, and Plants. There's nothing equal to it for Mealy Bug, Scale, Thrip, etc. XL ALL NICOTINE VAPORISING FUMIGATOR, either in Liquid or Cake, is still unsurpassed. Please order from your Nurseryman, Seedsman or Florist.—Manufacturer, G. H. RICHARDS, 234, Borough High Street, London, S.E.1.

WM. DUNCAN TUCKER AND SONS, LTD., Lawrence Road, South Tottenham, N.15; Conservatories, Winter Gardens, Vineries, Peach-houses, Portable Buildings, etc.

BULL'S NEW WHITE FLY VAPOUR

The instantaneous White Fly Eradicator which renders the extermination of White Fly so simple —merely sprinkle the greenhouse paths with the liquid, according to directions on every bottle and can :—

¼-pint **1/-**	1 pint **2/6**	½-gallon **7/6**
½-pint **1/6**	1 quart **4/6**	1 gallon **13/6**

BULL'S FOOD FOR PLANTS

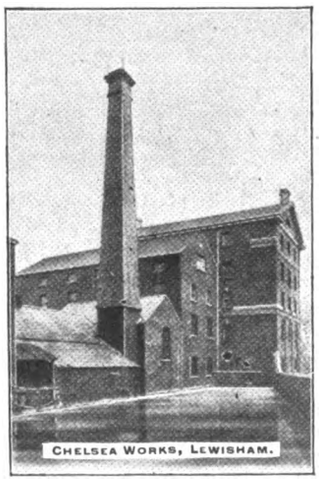
The National Fertiliser.

For very many years, this has been the Market Growers' Favourite Fertiliser, and it has meritoriously grown in such public demand that there is hardly a Seedsman or Nurseryman who does not stock this indispensable Organic Fertiliser.

Per Cwt. **32/-**	28 lbs. **9/-**	7 lbs. **3/6**
56 lbs. **16/6**	14 lbs. **5/-**	Tins, **10d., 1/8** & **3/6**

BULL'S FUMIGATING SHRED

Has established the great reputation of being the most efficient fumigating shred, destructive to all Insect Pests in greenhouses. It is easily applied—no apparatus being required—merely place the Shred in heaps on the ground, light in 3 or 4 places, extinguish the flame, and leave to smoulder.



In sealed packets sufficient for 1,250 cubic feet, **10d.**
For 3,000 .... **1/8**
For 10,000 .... **3/6**
Above double strength, for 20,000 cubic feet, per lb. **7/6**

These great Specialities are Manufactured at Chelsea Works, Lewisham, S.E., and supplied by all Seedsmen and Nurserymen throughout the Kingdom.

Sole Manufacturers :—

BULL'S PLANT FOOD Co.

SUTTON & SONS, THE KING'S SEEDSMEN READING

SUTTON'S

Record of Improvements in

GARDEN PEAS

Could the history of the evolution of the Garden Pea be written it would afford a story of unusual interest. At one time the varieties available scarcely exceeded a dozen in number, and these produced peas of a quality which would now be considered only fit for boiling in a dry state. But in the hands of experts such wonderful improvements have been achieved that the high-class Peas of the present day resemble their progenitors in hardly any one characteristic. Not less remarkable than the attainment of superb table quality is the extraordinary development in the size of the pods and the peas in them. Our well-known Pea, The V.C., is the largest-podded variety in cultivation, and customers have grown magnificent pods up to nine inches in length. The duration of the Pea crop has also been greatly extended, and by growing suitable varieties it is now possible to obtain supplies from the open ground from May to November.

THOUSANDS OF FIRST PRIZES

HUNDREDS OF GOLD MEDALS

Shrewsbury Floral Fete, 1922

CHAMPION PRIZE FOR VEGETABLES

Won by Mr. J. Jones, The Gardens, Ammanford, who writes:—

"In addition to winning the Champion Prize open to all, for 12 varieties of Vegetables at Shrewsbury Floral Fete, 1922, of which I feel very proud, I also gained First Prize, £5 and Silver Bowl, value £5 5s. od. at Llandilo Horticultural Show, 1922, for what was undoubtedly the finest collection of Vegetables put up in South Wales, comprising 38 varieties (see illustration below) all grown from Webbs' Seeds, which have given me the utmost satisfaction."

THE CHAMPION PRIZE COLLECTION AT SHREWSBURY comprised the following:

PEA—Webbs' Stourbridge Marrow - - - 4/6 qt.	**BEAN**—Webbs' Exhibition Runner - - - 2/6 pkt.
CAULIFLOWER—Webbs' Early Mammoth 1/6 pkt.	**CUCUMBER**—Webbs' Everbearing - - - 1/6 pkt.
CARROT—Webbs' Prizewinner - - - - 1/3 oz.	**CELERY**—Webbs' Perfection Pink - - - 1/- pkt.
LEEK—Webbs' Champion Prize - - - - 1/6 pkt.	**ONION**—Webbs' Seld. Ailsa Craig - - - 2/6 pkt.
PARSNIPS—Webbs' New Marrowfat - - 1/3 oz.	**POTATO**—Webbs' Goldfinder - - - 4/- for 14 lbs.
TOMATO—Webbs' Conqueror - - - - - 1/6 pkt.	**TURNIP**—Webbs' Silver Ball - - - - - 8d. oz.

CUT FLOWERS.

REMARKS.—With the exception of Roses there did not appear to be any particular shortage in this department for the New Year festivities. Disbudded Chrysanthemum blooms are still on sale in good condition; the principal sorts in white are Chestnut White and Pasckoucke. Coloured varieties begin to show signs of the end of the season. Of bunch blooms Heston White and Winter Cheer (pink), and Nagoya (yellow) are the best varieties. Daffodils, Hyacinths, Tulips and Freesias are daily increasing in numbers, and prices are falling. Small consignments of yellow and white Narcissi are arriving in good condition from the Channel Islands; also a few boxes of Blue Irises. The quantities of Richardias (Arums) and Lilium longiflorum have been sufficient to meet all requirements both for the Christmas and New Year trade, and their prices remained moderate. Increased supplies of flowers came to hand from across the water, but prices showed a tendency to rise on Friday and Saturday last. Scarlet Ranunculus and Anemones were much in demand, also Violets, Acacia (Mimosa), and Paper White Narcissus.

No. 1931. Vol. LXXIV. (THIRD SERIES) SATURDAY, DECEMBER 29, 1923. Registered as a Newspaper. PRICE 6d. POST FREE 7d.

SUBSCRIPTIONS—Inland or Foreign 30/- per annum, post free. *Entered at New York Post Office as second-class matter.*

Postal Address—5, Tavistock Street, Covent Garden, W.C. 2. Telegraphic Address—"Gardchron, Rand, London." Telephone—Gerrard 1543.

XL ALL!—When considering the purchase of a dressing for dormant fruit trees and bushes please remember the merits of XL ALL WINTER WASH. It thoroughly cleanses and prepares the trees and bushes for a clean, healthy start in the Spring, greatly minimising an early attack of insects. For American Blight, use it as soon as possible after the leaves have fallen. XL ALL LIQUID NICOTINE INSECTICIDE provides the finest dressing for Vines, Figs, Peach Trees, and Plants. There's nothing equal to it for Mealy Bug, Scale, Thrip, etc. XL ALL NICOTINE VAPORISING FUMIGATOR, either in Liquid or Cake, is still unsurpassed. Please order from your Nurseryman, Seedsman or Florist.—Manufacturers: G. H. RICHARDS LTD., 234, Borough High Street, London, S.E.1.

PERPETUAL-FLOWERING CARNATIONS for the greenhouse and the garden; catalogue free on application.—C. ENGELMANN, Carnation Grower, Saffron Walden, Essex.

BARR'S SPECIAL OFFER of SURPLUS SPRING-FLOWERING BULBS—Daffodils, Hyacinths, Tulips, Crocuses, Snowdrops, etc. All selected bulbs in fine condition at GREATLY REDUCED PRICES. List on application.

BARR'S SURPLUS HARDY PLANTS for Flower Border and Rock Garden, including fine selections of Irises, Michaelmas Daisies, Aubrietias, Hellanthemums, etc., etc. List on application.—BARR & SONS, King Street, Covent Garden, W.C. 2.

WATERER'S Gold Medal Rhododendrons, Azaleas and Roses, rare Hardy Shrubs, Fruit Trees, Berries, etc., Alpine and Perennial Plants, Vegetable and Flower Seeds, Scotch grown Seed Potatoes. Catalogue free.—JOHN WATERER, SONS & CRISP, LIMITED, Twyford, Berks; Bagshot, Surrey; and London.

DOBBIE'S 1924 CATALOGUE and GUIDE TO GARDENING: 130 pages, over 160 illustrations. Send to-day mentioning "Gardeners' Chronicle" and you shall have a Free Copy per return post.—DOBBIE & CO., LTD., Seedsmen to H.M. The King, Edinburgh.

LAXTON'S FRUIT TREES, Strawberries and Small Fruits, including many fine novelties for 1923. Our trees are exceptionally fine this season. Catalogues gratis. Full cultural instructions for 2d. postage.—LAXTON BROTHERS, Bedford.

CHOICE NEW CHRYSANTHEMUMS.—Our Catalogue of nearly 800 varieties, including splendid novelties for 1924 (also new Dahlias, Pelargoniums, etc.) is now ready. Post free.—J. W. COLE & SON, Westwood Nurseries, Peterborough.

SYDENHAM'S EARLY FLOWERING CHRYSANTHEMUMS are still as good as any procurable. List on application. 12 finest 4/-; 25 8/-; 50 in 25 pairs, 15/-; 100 in 50 pairs, 27/6. All carriage paid; satisfaction guaranteed.—WILLIAM SYDENHAM, Melbourne, Derby.

THE POSSIBILITIES of VEGETABLE CULTURE is made very evident in our new SEED CATALOGUE. For example: a photograph is reproduced (actual size) of a Bean of our "Colossal" Runner nearly 19 inches long; a beautiful and model bulb of our "Premier" Onion below actual size. For the first time we illustrate a bulb of our "Royal Keeper," a remarkable keeping and cropping Onion, also a bulb of the true type of Cocoa-Nut which we have been selecting for many years. On the front of this Catalogue is shown, from a photograph sent by one of our customers, a bed of our "Premier" onion in extent and of a quality rarely, if ever, seen in combination. "Premier" Onion, so well known, is the standard of excellence of all our vegetables. This Catalogue is quite free.

DICKSON & ROBINSON, MANCHESTER. The King's Seedsmen.

NOW IS THE TIME TO PLANT A

KELWAY COLOUR BORDER, to include our world-renowned specialities—Paeonies, Delphiniums, Pyrethrums, Gaillardias, Phloxes, etc., etc. Borders of any kind can be arranged. Write us with your ideas and we will quote. Please give this attention now.—KELWAY & SON, The Royal Horticulturists, Langport, Somerset.

CHRISTMAS.

The Christmas season is often considered in the light of a breathing space, for business man and craftsman alike; yet even at this festive time there is work waiting to be done. In the case of the advertiser, the New Year's campaign has to be planned, new and improved copy and blocks prepared, spaces taken in the best journals, and appropriations assigned. Unless this is done in good time, others are beforehand, the best spaces are taken, and the cream of the New Year market skimmed. In advertising, as in most things, timely preparation reaps a rich reward.

NOW IS THE TIME TO PLANT KELWAY'S

PAEONIES & DELPHINIUMS.

	DOZEN.		DOZEN.
Coll. "F"	100/-	Coll. "F"	80/-
Coll. "E"	80/-	Coll. "E"	50/-
Coll. "D"	50/-	Coll. "D"	40/-
Coll. "C"	36/-	Coll. "C"	30/-
Coll. "B"	27/-	Coll. "B"	24/-
Coll. "A"	16/-	Coll. "A"	16/-

All improved named varieties. Fine, strong plants, to flower next year.

KELWAY & SON, LANGPORT, SOMERSET.

SANDERS, ORCHID GROWERS, St. Albans.

SUTTON'S VEGETABLE SEEDS

Sutton's Seeds

BY APPOINTMENT.

FOR very many years "Sutton's" have been famed for the superior character of their strains of Vegetable Seeds, and the result of years of unremitting labour in cross-breeding and selection has never been more apparent than in the stocks now offered.

The high quality of "Sutton's Seeds" has been proved conclusively on the exhibition stage at all the leading shows of the country, and our GOLD MEDAL DISPLAY, and the wonderful Collection of Vegetables staged by our valued Customer The Hon. Vicary Gibbs (Head Gardener, Mr. E. Beckett) which was awarded the CORONATION CUP and GOLD MEDAL at the Royal Horticultural Society's Autumn Show, 1923, will be remembered by all visitors.

NEW
Knapsack Sprayers
Less than Half Price

An Exceptional Opportunity

A good sprayer is absolutely essential in every garden. During the war we supplied a considerable number of our well-known Four Oaks Knapsack Sprayers—Rubber diaphragm type — to the Government, and we have just repurchased a small quantity back again **which have never been used.** They are made of copper, but painted service grey colour. They possess various special additions to the ordinary machines, and the price to-day would be £5 each machine.

We guarantee them to be in perfect working order as new. We will send one machine carefully packed and carriage paid for 50s. Cash with order, or two machines for 90s., but cash must accompany all orders.

Please mention this paper.

FOR 2000 CUBIC FEET 2/6 EACH.

NOTES FROM MAIDSTONE.

CURRANTS ON WALLS.

Dr. Johnson, while appreciating Mrs. Thrale's Peaches, was a great lover of Red Currants.

As grown on walls they attain a size and flavour which makes them a dessert fruit,

We have good Fan Trained Trees of Fay's Prolific, Prince Albert (very late), Scotch Red, Raby Castle, Skinners' Early and Utrecht at 3/6 each; larger trees 5/- each.

Planting can be done now when weather is open.

WILLIS BROS.'
Garden Fertiliser

A Real Manure. Not a Substitute.

NO STABLE MANURE REQUIRED.

For digging in or as a top dressing. For Kitchen Garden and Herbaceous Borders. We are constantly receiving orders and testimonials from satisfied users both on heavy and light soils. 1 cwt., 17/6; ½-cwt., 10/-; 28 lb., 6/-; per ton. £16 10s. All carriage paid.

LAWN MANURE.

Having been connected with the experimental Manuring of pastures, etc., for over 40 years, we are in the position to offer you the above with perfect confidence as to results.

Specially suitable for poor mossy lawns; improves the texture of the grass, and helps the lawns to keep their colour in dry seasons. Can be used at the rate of 5 cwt. to the acre.

1 cwt. bags, 20/-; 56 lbs., 11/-; 1 ton, £19; 10 cwt., £9 15s. Carriage paid. We quote special prices for Grass Manures for Park Land in quantities.

ANTI-CLOVER MIXTURE.

Specially prepared for Golf Greens, Tennis Courts and Bowling Greens. This mixture will check the growth of clover, and after one or two dressings the clover will be found to have disappeared, leaving a fine grass. Should be used at the rate of three to four ounces per square yard. 1 cwt. bags, 30/-; 56 lbs. 16/-; carriage paid.

SPECIALLY SELECTED LAWN GRASS SEED.

For Tennis Courts, Bowling Greens, and Golf Courses, and Renovating Lawns. Per lb., 2/6; 14 lbs., 30/-. Bags charged extra.

STRONG GROWING GRASS MIXTURE.

For growing under trees. Per lb., 2/6; 14 lbs., 30/-.

NEW RUSSIAN MATS.

7 ft. by 3 ft. 6 in., 20/- per doz. No full-sized Archangel Mats are being made.

HESSIAN MATS.

9 ft. by 4 ft. 6 in., 35/- per doz. Canvas Covers Tanned. PRICES ON APPLICATION.

BONE MEALS, SUPERPHOSPHATE, NITRATE OF SODA, SULPHATE OF AMMONIA, KAINIT, SULPHATE OF POTASH, BASIC SLAG, etc., supplied.

Send for our list of Garden Manures and Horticultural Sundries. Free on application.

HAWLMARK SEEDS

By Appointment to His Majesty.

The Results of a Century's Research

Genuine only from DICKSON'S, HAWLMARK, BELFAST.

Stop the Rot

Rot, decay and vermin are always watching for unprotected woodwork. "Sidol" foils them. This rich nut brown preservative penetrates, and converts sappy wood into long lived timber. Cheaper and more artistic than paint for interiors, bringing out the natural grain of the wood. Easy to apply, very long lasting. From 2/3 per qt. tin up to 3/- per gall. in 40 gall. barrels.

In standard shade of Nut Brown. Also in Green.
Stocked by Ironmongers and Colourmen.
Write for Booklet to Dept. 24.

CALENDAR OF GARDEN OPERATIONS.

Price **2/11** *post free.*

SINCE the new edition of this book was published it has deservedly regained and surpassed its former popularity, and is now acknowledged to be far and away the best book for the small gardener and allotment holder. There is no difficulty in finding any particular operation required, for the book is divided into twelve months, showing what has to be done in the garden each month. Besides this, there is an excellent index, a large number of useful illustrations, and many special articles of the greatest help and value.

GARDENERS' CHRONICLE, Ltd., 5, Tavistock Street, Covent Garden, W.C. 2.

Present-day Gardening Series.

Each Volume is written by an Expert, and Illustrated with Eight Plates reproduced from Colour Photographs by T. ERNEST WALTHAM, F.R.H.S.
